

TRENDS IN INCOME AND WEALTH INEQUALITY*

Moritz Kuhn[†]

First version: August, 2013

This version: May, 2014

preliminary and incomplete

Abstract

These notes provide an empirical overview on the trends in income and wealth inequality for the United States. The empirical results are based on household micro data from the Survey of Consumer Finances 1992 - 2010. In addition, I present new facts on the distribution of liquid assets in the cross-section and over time. I find that both income and wealth inequality have increased when looking at the Gini coefficient. The Great Recession has led to an increase in wealth inequality. The amount of liquid assets constitutes depending on the strictness of the liquidity definition either 40 % of networth or income.

1 Introduction

Over the past decades income and wealth inequality in the United States have increased. Economists have developed models to study the sources and the consequences of this rise in inequality. Ríos-Rull and Quadrini (2014) provide a comprehensive survey of the empirical and theoretical literature. Most of the empirical evidence discussed in their survey is based on results from these notes. At the current stage, these notes provide a purely descriptive analysis of the data. The results might be of interest to other researchers. The focus in these notes is on four measures of wealth and income: (1) *networth* as the consolidated wealth of a household including all assets and debt (except claims to social security); (2) *non-housing networth* (NHW) that subtracts the home equity value from networth; (3) *earnings* as measure of labor market income including an imputed share of business income; and (4) *income* as a comprehensive measure of income flows to the household including among others transfers and capital income.

The key findings are: (1) wealth and income inequality as measured by the Gini coefficient have increased; (2) NHW is more unequally distributed than networth; (3) earnings are more unequally distributed than income; (4) until 2010 home equity was positive throughout the wealth and income distribution; (5) liquidity in its broadest definition constitutes 46 % of networth and liquidity in its strictest definition constitutes only 39 % of earnings.

I provide an empirical overview of the trends of the earnings, income, and networth distribution for the last two decades using data from the Survey of Consumer Finances from 1992 to 2010. I follow Díaz-Giménez, Glover, and Ríos-Rull (2011) and provide separate results for the income and wealth distribution if households are sorted by their position in the earnings, income, and networth distribution to distinguish between households that are income or wealth poor (rich). Many of the empirical results presented below will remain undiscussed at the moment. These results report the wealth and income distribution by household characteristics. The household characteristics for which results are provided are age of household head, education of household head, labor market group of household head, marital status, and self-assessed health status of the household head. In addition, I provide results on the evolution of housing wealth and mortgages as the two single most important gross positions in the balance sheets of U.S. households. Kaplan and Violante (2014) have recently argued that a more detailed modeling of households' balance sheets is important to understand phenomena like the consumption response to fiscal policy.

I provide results and a short discussion on the distribution of liquidity along the wealth and income distribution. These results have to the best of my knowledge not yet been

documented elsewhere in the literature. I also provide detailed results on the top 1 % of the income and wealth distribution. Although only a small fraction of the population, they possess more than 30 % of networth and receive more than 15 % of earnings and income. The remainder of these notes has the following structure: In section 2, the data is described. Section 3 discusses the empirical results. Section 4 constructs measures of liquidity and discusses the findings for these measures. Section 7 provides some concluding remarks. All tables can be found in the appendix.

2 Data

The data comes from the 1992 to 2010 Survey of Consumer Finances (SCF). The SCF is a representative triennial household survey that provides comprehensive information on the U.S. households' income and wealth situation. Due to its sampling scheme, the SCF provides a comprehensive picture of wealth of households including the very wealthy households (Kennickell (2008)). Income information in the SCF always refers to the previous calendar year and I adjust all data to real 2007 Dollars using the CPI index (CPI-U-RS). The definitions of portfolio positions used in this note follow the definitions of the bulletin reports of the Federal Reserve Board.¹

Four variables are at the focus of the first part: networth, non-housing networth, earnings, and income. Networth constitutes a consolidated measure of households' wealth excluding claims against social security. The different components of networth provide a detailed picture of households' balance sheets. Figure 1 provides a graphical illustration of the balance sheet positions of households in the data. Non-housing networth is networth net of houses, mortgages, and home equity lines of credit. Earnings are constructed as in Díaz-Giménez, Glover, and Ríos-Rull (2011). I impute a share of business income to labor income to construct earnings. The share of business income that is imputed to labor income is the share of unambiguous labor income in the sum of unambiguous capital income and labor income.² The shares for the different years from 1992 to 2010 are 89.9 %, 89.8 %, 88.7 %, 86.3 %, 91.3 %, 86.3 %, and 93.4 %. Income is the sum of all income components in the

¹For the most recent report see Bricker, Kennickell, Moore, and Sabelhaus (2012). If definitions change over time, I use for each year the most recent available definition at that time. I deviate from the definitions of income classes after 2004 and include pension withdrawals in other income instead of including it into social security income as done in the bulletin articles.

²Unambiguous labor income are wages and salaries and unambiguous capital income is the sum of dividends, interest income, and capital gains.

Survey of Consumer Finances.³ The main difference between earnings and income is that income includes among others transfers, capital income, and withdrawals from retirement accounts.⁴

To construct a measure of revolving debt, I follow Telyukova (2013) based on SCF questions on credit card balances. The same is done by Kaplan and Violante (2014). Revolving debt is credit card debt where the total balance is not always or almost always paid off at the end of the month. Hence, revolving debt constitutes a fraction of credit card debt. For the time period from 1992 - 2010 the share of credit card debt that is categorized as revolving debt is roughly 70 %. The net value of cars that I use below to construct liquidity measures is the value of the car net of vehicle installment loans that are part of the installment loan position of debt in figure 1.

Below, I report income and wealth at different points in the earnings distribution to compare households with low earnings to households with high earnings with respect to their income and networth. Earnings are zero for a substantial fraction of households in the population if there is ambiguity regarding the ordering of households according to earnings, I will use income to sort households with identical earnings. For income and networth this problem is only of minor importance. If necessary, I use earnings in case of identical networth (income) to sort along the networth (income) dimension. My results differ from the results in Díaz-Giménez, Glover, and Ríos-Rull (2011) who use a different sorting rule.

3 Results and discussion

This section discusses first the distribution of earnings, income, and networth. In the second step, I discuss a set of statistics commonly used to measure the degree of inequality and the shape of the distribution. In the third step, I examine the distribution of houses and mortgages as the two single most important gross positions of networth.

3.1 Mean income and wealth

Table 1 shows different quantiles of the earnings, income, networth, and non-housing networth distribution in thousands of constant 2007 Dollars. I show data separately for each

³In some cases, total income reported in the SCF is not equal to the sum of reported income components. The income components are labor income (wages and salaries), business and farm income, dividends, interest income, capital gains, and transfers. See SCF documentation for more details.

⁴In the absence of more terms, I will refer to “income” in general if I discuss financial flows to households, even if this flow contains less income sources, e.g. only earnings.

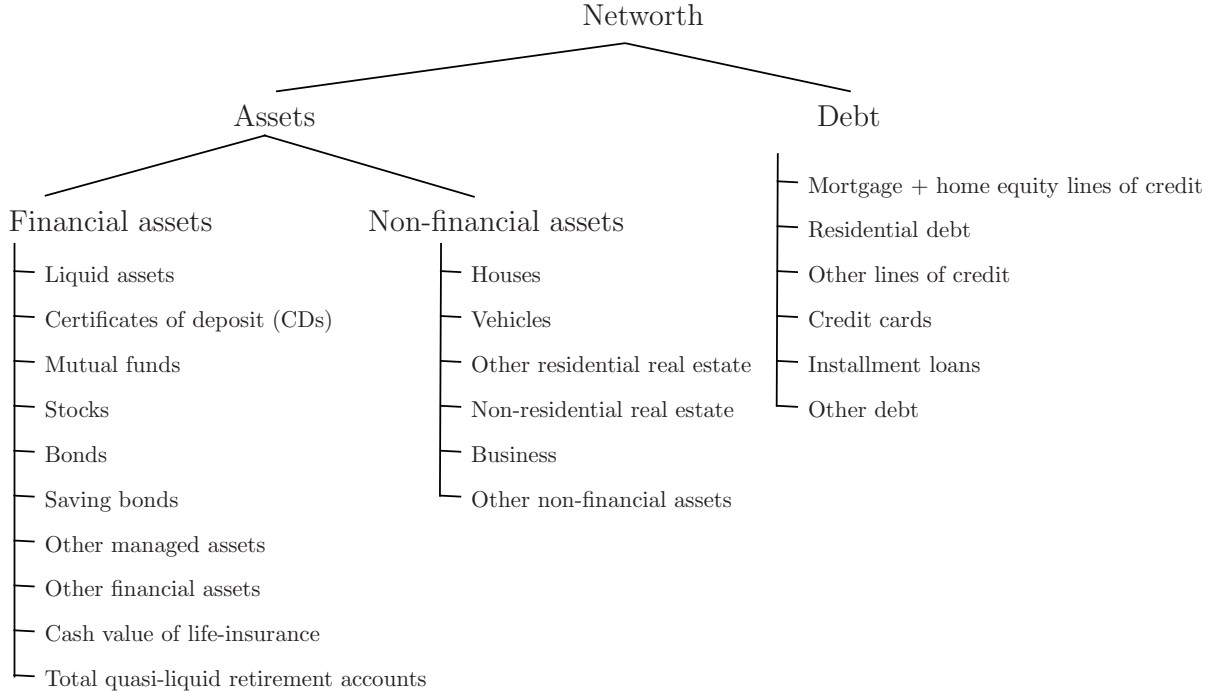

Figure 1: SCF household portfolio

year. All tables have the same structure. They start from the left with detailed information on the distribution within the lowest quintile of the distribution. In the middle part of the distribution, the values for all five quintiles of the distribution are shown. The right part provides detailed information on the distribution within the highest quintile of the distribution. This structure of the tables is taken from Díaz-Giménez, Glover, and Ríos-Rull (2011). Several facts stand out. Earnings in the lowest quintile are zero.⁵ These are households without any wage or salary income. Lowest earnings are always negative resulting from negative imputed business income. Income is only negative at the lowest realization but is positive starting from the first centile. As we will see below, these are wealthy households so that negative income means a reduction in wealth for them. Income includes transfers, social security benefits, and pension withdrawals so that households that are temporary or permanently not active in the labor market have some income although earnings might be zero. Table 4 shows that transfers and other income are the most important income source for households in the lower quintile of the earnings distribution.⁶

⁵Negative earnings arise if in the imputation step business income is very negative compared to other wage and salary income.

⁶Withdrawals from retirement accounts are always part of other income.

Looking at networth, we see that about 10 % of households have zero or negative networth. Looking therefore at networth would identify at most 10 % of the population as being borrowing constrained. Kaplan and Violante (2014) look at liquid assets of households to determine if a household is constrained in its consumption choice. They document based on the SCF that a substantially larger fraction of the population is what they call *wealthy hand to mouth* consumers. I discuss the distribution of liquid assets in section 4. If we look at NHW as measure of households' wealth, we find that the level of wealth goes down and it seems as if the share with zero or negative wealth increases slightly. Still, less than 20 % of the population would be borrowing constrained.

Looking at the top of the distribution, we see that networth increases more strongly in terms of the 99 to 90 percentile ratio than earnings or income. I refer to the 99 to 90 percentile ratio as the right tail of the distribution and call it long if the ratio is large. For example, the 99 to 90 percentile for earnings in 1992 is roughly 3 (344.2/107.9) and it is more than 6 for networth (3359.7/517.9). In terms of this measure, NHW has to steepest increase and the longest right tail. Looking at income and earnings, I find that both have similar right tails in terms of the 99 to 90 percentile ratios.

Looking at the consequences of the Great Recession by comparing data from 2007 and 2010 from table 1, we see a strong decline of networth at the lower end of the networth distribution. Negative positions roughly double and positive positions decrease by almost half up to the second quintile. At the upper part of the distribution, wealth losses have been less severe. NHW and networth have been similarly affected by the financial crisis. Throughout the distribution, earnings and income decreased only slightly.

Comparing the growth rates of the different quantiles of the distribution, we see that up to the 60th percentile earnings did not grow between 1998 and 2007 while they grew by 10 % and more starting from the 80th percentile. The 99th percentile shows the strongest increase with a growth rate of more than 25 %. For the growth rates of the income percentiles we find a much more uniform distribution. Even the low percentiles experienced growth rates in excess of 25 %. Finally, looking at networth shows that over the same time period negative networth at the lowest centile increased, netowrth up to the 20th percentile remained roughly constant, while networth in the middle and at the top of the distribution increased by up to 73 % at the 99th percentile. Table 7 suggests that the strong increase in networth relative to income and earnings has been largely driven by the increase in home equity (houses minus mortgages).

3.2 Income and wealth inequality

Table 2 shows widely used measures of inequality and the shape of the distribution.

NHW, which consists mainly of financial wealth and car equity, is the most unequally distributed wealth measure when looking at the Gini coefficient (min. (1992 - 2001): 0.86; max. (2010): 0.89). Including home equity decreases inequality (min. (1992 - 1995): 0.79; max. (2010): 0.85) but is still larger than for income (min. (2004): 0.54, max. (1992, 2001, 2007): 0.57) or earnings (min. (1998): 0.61 ; max. (2010): 0.65).

The distributions of networth and NHW are positively skewed with a long right tail. Looking at networth, the mean-to-median ratio, a standard measure of skewness, varies between 3.68 in 1995 and 4.82 in 2004 but increased to 6.42 in 2010. The ratio of the mean in the highest centile to the mean in the bottom two quintiles (Top1toBottom40) varied between 951 in 1992 and 1,522 in 2007 but increased to 47,534 following the Great Recession in 2010. Looking at NHW, the mean-to-median ratio varies between 7.43 in 1995 and 13.18 in 2010. The ratio of the mean in the highest centile to the mean in the bottom two quintiles (Top1toBottom40) is highly volatile and changing from positive to negative numbers because the bottom of the distribution holds little or negative NHW.

Looking at the Gini coefficient for income and earnings, income that includes transfers and capital income is the least unequally distributed. The Gini coefficient for earnings, that include a share of business income, is stable between 1992 (0.63) and 2007 (0.64). In 2010, it increases only slightly to 0.65. Income inequality is stable starting from 0.57 in 1992 and being 0.55 in 2010. Another widely used measure for income inequality is the variance of log income. In case of negative income observations, this measure is problematic because the logarithm of a negative number is not defined so that all observations with negative income are dropped. When looking at the variance of log income, I find that it decreases from 1.2 in 1992 to 0.92 in 2010. Looking at the variance of log earnings, I find that it remains roughly constant at 1.36 in 1992 and 1.41 in 2010.

In tables 3 - 8, I follow Díaz-Giménez, Glover, and Ríos-Rull (2011) and sort households according to their position in the earnings, income, or wealth distribution. They refer to the households sorted according to earnings as the earnings-poor and the earnings-rich, for income as the income-poor and the income-rich, and accordingly for networth as the wealth-poor and the wealth-rich. This distinction is important because as we will see who is poor depends on the dimension that is considered and there are not “the poor”. In table 3 ,households are sorted according to their position in the earnings distribution. Tables 5 and 8 show the distribution if households are sorted according to their income or networth.

Looking at households sorted by earnings, we see that income, networth, and NHW are lower at the bottom of the distribution. All increase along the earnings distribution. Only at the lowest centile networth and NHW are high because these are households with negative business income which leads to negative earnings and they have a substantial amount of wealth. Their networth and NHW corresponds roughly to the 90-95 percentile in the earnings distribution. Negative earnings result for them in a decrease in their wealth. A similar picture arises from table 5 where households are sorted according to their position in the income distribution. Notably, networth and NHW in the lowest income centile are now lower than in the lowest earnings centile. Table 8 sorts households by networth. Earnings and income decrease over the first quintile and start to increase only from the second quintile. Networth and NHW are negative up to the first quintile and very similar in level. Starting from the second quintile both are positive and start diverging with networth exceeding NHW. This still holds in 2010. Note that in table 1 where NHW exceeded networth households have been separately sorted by NHW and networth while now NHW is also sorted according to networth.

Looking at the consequences on networth from the Great recession in Table 5 by comparing networth at different positions in the income distribution between 2007 and 2010, we see that up to the 3rd quintile networth changes relative to income are about 35 % of annual income if averaged over the three bottom quintiles. In the upper part of the distribution losses exceed one annual income and are about 120 % of annual income. Looking only at averages in the last column the changes in networth are roughly equal to one annual 2007 income. Unfortunately, this comparison is based on the comparison on repeated cross sections and detailed analysis using panel data is possible based on the SCF 2007 - 2009 panel. I plan to explore this further in the future.

3.3 Houses and mortgages

The net position of houses and mortgages constitutes the households equity in the house.⁷ The difference between networth and NHW is home equity. Looking at table 1, we see that the value of houses always exceeds the value of mortgages. The share of the mortgage to the value of the house increases with earnings, i.e. households with the lowest earnings have the lowest loan to value ratio. We have already seen that households at the lower end of the earnings distribution are households with zero earnings and only transfer income or from withdrawals from retirement accounts. These households are likely also households that have

⁷Mortgages include home equity lines of credit.

already paid off a substantial amount of their initial mortgage. When we sort households by networth as in table 8, we find that low networth households have higher loan to value ratios with values close to 1. In 2010, the lowest networth quantile has negative home equity with mortgages exceeding house values.

4 Liquidity

Recently, Kaplan and Violante (2014) have stressed the importance of the extend of liquid assets in the households portfolio to understand for example the reaction of households to fiscal transfers. I discuss four measures of liquidity and how they involved over time. These measures are mainly based on Koehne and Kuhn (2014) (KK). KK report results for 2004 and apply a sample selection focusing on households in the labor market. Here, I report results without any sample selection and over time. I construct two additional measures of liquidity. It turns out that it is crucial how retirement assets are accounted for in the households' balance sheets when it comes to measuring liquidity.

As a benchmark, I construct liquidity measure L0 that contains only transaction accounts (checking, saving, money market, call accounts). L0 constitutes the strictest definition of liquid wealth. I then follow KK in constructing other measures of liquid wealth. L1 adds to L0 tradable assets like mutual funds, stocks, bonds; revolving debt is subtracted. This definition is identical to the liquidity definition Kaplan and Violante (2014). The next measure L2 adds to L1 the value of cars net of debt. This liquidity measure is based on the idea that in case of financial hardship households can sell durable consumption goods. In the SCF, cars are the only itemized durable consumption good. L2 is the preferred liquidity measure in KK. In addition to KK, I construct a measure L2a that includes instead of the equity value of cars the value of retirement liquid assets. There are two reasons to do this. First, these accounts can be accessed without costs (except for paying income taxes) starting from roughly age 60. This shows up in the income measure that is positive for households without earnings but who withdraw funds from their retirement accounts. Second, households can borrow against these accounts for a limited time period (usually up to 5 years) without incurring substantial costs. The broadest measure of liquidity (L3) adds to L2 certificates of deposit, retirement liquid assets, saving bonds, cash value of life insurance, other managed investment, and other financial assets. This measure includes all financial assets plus the net value of cars with revolving debt subtracted.

4.1 Results

Comparing 3 to 10 shows that liquid assets using even the broadest definition L3 are only a fraction of networth (min. (1992): 0.40, max. (2001): 0.51). Second, if we consider the strictest definition of liquidity, then this corresponds only to a fraction of earnings (min. (1995): 0.33, max. (2010): 0.48). The three intermediate measures L1, L2, and L2a differ by a factor of 1.5 with L2 being always in between L1 and L2a.

Looking across the earnings distribution in table 10, we find that at the lower end of the distribution households hold high liquidity. These are most likely households that incurred negative business income. Starting from the 1st centile, L0 is only increasing slightly. L1, L2, and L2a increase from the first to the second quintile, are slightly increasing from the 3rd to the 4th quintile and are then strongly increasing in the upper end of the earnings distribution.

Looking across the income distribution in table 11, we find that the spike in liquidity at the lower end of the distribution decreases and that liquidity increases uniformly with income. Looking at networth in table 15, the pattern from table 11 is reinforced. Up to the second quintile households hold very little liquidity. Using measure L1 as in Kaplan and Violante (2014), the lowest quintile holds negative liquidity and even at the 2nd lowest quintile households hold only a few thousand dollars of liquid wealth. Even the broader measures L2 and L2a indicate that at the bottom of the distribution liquidity is low compared to income in table 10. Table 15 shows that liquidity and networth are highly correlated and households with low networth hold on average also low liquidity. Indeed, liquidity independent of the definition is low at the bottom of the networth distribution.

5 The richest

Tables 12 to 14 show the share of earnings, income, and networth of the top households in the distribution. We see that networth is the most unequally distributed with the top 1 % of the distribution owning more than 30 % of networth, in case of income and earnings slightly more than 15 % of income accrue to the top 1 %. Looking at the top 0.1 %, we see that still more than 10 % are owned by this group, for income and earnings the share that accrues to the top 0.1 % is more than 5.5 %. As in the case of the top 1 %, the share for income is roughly half of that of networth.

6 Further results

As already mentioned in the introduction many of the results from the empirical analysis remain undiscussed at the moment. The interested reader might consult the tables and explore them on his or her own. Tables 18 - 32 follow the same structure as the tables discussed in this note but condition on different household characteristics. The household characteristics for which results are provided are age of household head, education of household head, labor market group of household head, marital status, and self-assessed health status of the household head. I plan to extend these notes in the future to add some discussion on these results.

7 Concluding remarks

These notes provide an empirical review of wealth and income inequality in the United States over the past 20 years. I document that wealth is more unequally distributed than income and that following the Great Recession wealth inequality has further increased while income inequality seemed to not increase. Recent research by Kaplan and Violante (2014) has highlighted the importance of liquid assets in households' balance sheets to assess the impact of fiscal policy. I provide several measures for liquidity and discuss their distribution and evolution over time.
