Legal Unbundling can be a Golden Mean between Vertical Integration and Separation

Felix Höffler[1] and Sebastian Kranz[2]

November 2007

Abstract

We study an industry in which an upstream monopolist supplies an essential input at a regulated price to several downstream firms. Legal unbundling means that a downstream firm owns the upstream firm, but this upstream firm is legally independent and maximizes its own upstream profits. We allow for non-tariff discrimination by the upstream firm and show that under quite general conditions legal unbundling yields (weakly) higher quantities in the downstream market than vertical separation and integration. Therefore, typically, consumer surplus will be largest under legal unbundling. Outcomes under legal unbundling are still advantageous when we allow for discriminatory capacity investments, investments into marginal cost reduction and investments into network reliability. If access prices are unregulated, however, legal unbundling may be quite undesirable.

Keywords: Network industries, regulation, vertical relations, investments, ownership, sabotage

JEL-Classification: D2, D4, L1, L42, L43, L51

1   Introduction

In many industries vertically integrated firms are not only active in the final product market, but they also supply essential inputs to potential downstream competitors. Prominent examples are network industries, like energy, rail, or telecommunications where access to a transmission or a railway network is an essential input. Another example is the software industry where, e.g., Microsoft offers "compatibility" to Windows and at the same time competes in the applications market. An important and heavily researched policy question is: should vertical integration be allowed? Standard arguments in favor of integration are that integration at least partially overcomes the double marginalization problem and that it might provide better investment incentives for the upstream operations. The main motivation to vertically separate an integrated firm is that integration can lead to discriminatory behavior against downstream competitors.

We analyze a third alternative: legal unbundling. Legal unbundling means that the essential input must be controlled by a legally independent entity with an autonomous management, but a firm that is active in the downstream market is still allowed to own this entity. Ownership under legal unbundling entitles the downstream firm to receive the entity's profits, but interferences in the entity's operations are forbidden.

Forms of legal unbundling are commonly observed in network industries. Legal unbundling is the current standard requirement for the energy industry in Europe, and the related concept of "Independent System Operators" is also an option in the proposals for a new EU regulation.[3] In the US, forms of legal unbundling exist for natural gas pipelines and in large parts of the electricity transmission systems that are operated by Regional Transmission Organizations or Independent System Operators.[4] Similar forms of "partial separation" are also common in the telecommunications industry in Europe and the US.[5]

Irrespective of how the industry is vertically structured, the price for the essential input is usually regulated. Typically, regulators use linear tariffs above

---

[3]For the electricity market, see Directive 2003/54/EC, Articles 10 (1) and 15 (1), for the gas market, see Directive 2003/55/EC, Articles 9 (1) and 13 (1) and the proposal to amend this Directive issued 2007-09-19.

[4]See Federal Energy Regulatory Commission, Order 636 (issued 1992-04-18) for natural gas and Order 2000 (issued 1999-12-20) for electricity transmission.

[5]For the US see Section 272 of the Telecommunications Act of 1996; for the European Union see Directive 2002/21/EC, Article 13 (1b).

the marginal cost, e.g., in order to allow for the coverage of fixed costs. While non-discrimination with respect to the access tariff is relatively easy to impose,[6] non-tariff discrimination remains an important problem in practice. Regulators and competitors report of such "sabotage" in form of discriminatory information flows, undue delays in delivery of the service, overly complex contractual requirements, requiring unreasonably high bank guarantees and the like.[7] Our research question therefore is: How does legal unbundling compare to the outcomes of vertical integration and vertical separation if access prices are regulated while non-tariff discrimination cannot be prevented?

To answer this, we propose a fairly general setup. There is one upstream monopolist (F_0), a potentially integrated affiliated downstream firm (F_1), the "incumbent", and $n-1$ potential downstream competitors. The upstream firm produces an essential input at constant marginal cost c_0, which the downstream firms need in a fixed proportion to produce the final output. We impose no other restriction on the downstream firms' technologies, in particular, some or all competitors might be more or less efficient than the incumbent F_1. In the downstream market, the incumbent moves first; no other restrictions are imposed on the downstream competition. Strategies could, for example, affect quantities, (non-linear) prices, investments or entry decisions. That the incumbent moves first is mainly a simplifying assumption; we exemplify with Cournot competition that the main results also apply with simultaneous moves in the downstream market.

The upstream firm F_0 sells the input to all downstream firms at a regulated linear access price a above marginal costs (we also extend this setup to more general forms of price regulation). Although price discrimination is not possible,

_____

[6]Although this also can be an issue, e.g., if non-linear tariffs are used. They might be tailored such that only the subsidiary of the integrated company can realize low prices. Exactly for this reason, regulators are skeptical about such tariffs. See, e.g., European Commission, Energy Sector Inquiry, Competition report on energy sector inquiry (Jan. 10, 2007), part 1, para 155, p. 58. One example was the access to the Deutsche Telekom network required to offer narrowband internet access (a product called T-Online-Connect-Interconnect), where Deutsche Telekom offered quantity rebates which were only realized by its own subsidiary "T-Online". The regulatory authority ruled this to be discriminatory. See the German regulator's annual report "Tätigkeitsbericht 1998/99", p. 67.

[7]See, e.g., European Commission, Energy Sector Inquiry (Jan. 10, 2007), Competition report on energy sector inquiry, part 1, para 169, or para 493, p. 163: For the Telecommunications sector, see for instance a submission of the VATM (Association of competitors to Deutsche Telekom) to the European Commission, "Markteintrittsbarrieren im deutschen Telekommunikationsmarkt", September 2001.

F_0 can "sabotage" the downstream firms, i.e., it can influence the cost and demand situation of each downstream firm.

Four different vertical structures are compared: integration of F_0 and F_1; separation (i.e., all firms are independent); legal unbundling (F_0 is legally independent and maximizes its own profits but is owned by F_1); additionally, we discuss also "reverse unbundling" where the downstream firm is legally unbundled — although this seems to be of less relevance in practice.

Our main result is that legal unbundling leads to (weakly) higher levels of output than all the other vertical structures. In many cases, higher output will translate into (weakly) higher consumer surplus under legal unbundling. The intuition why legal unbundling leads to higher quantities than vertical integration is as follows. Due to the access price regulation, upstream profits of F_0 are maximized when total output is maximal. Thus, if F_0 is legally unbundled, it wants to maximize total output and refrains from sabotage of the downstream firms. In contrast, with vertical integration, F_0 also takes into account downstream profits of F_1 and may engage in sabotage of downstream competitors in order to increase downstream profits. We call this the *"sabotage effect"*.

When comparing legal unbundling to vertical separation, more complex forces are at work. First, since in both cases the upstream firm wants to maximize total output, neither under legal unbundling nor under vertical separation will the upstream (usually) sabotage downstream firms, i.e., there is essentially no sabotage effect.

Second, while a vertically separated downstream firm F_1 is interested only in its own profits, under legal unbundling F_1 also has an interest in high upstream profits — and thereby in a high overall output. Under legal unbundling, the downstream firm F_1 will therefore select strategies that yield higher total output compared to separation. We call this the *"downstream expansion effect"*.

Part of the downstream expansion effect is explained by the well-known intuition from the double marginalization problem: Under legal unbundling the incumbent calculates with the true input costs c_0 instead — as under separation — with the higher access price a and is therefore willing to expand output. The incumbent, however, takes additionally into account that he can induce an output change by downstream competitors. We call this the *"induced output effect"*. For instance, in the case of legal unbundling and price competition, the incumbent sets a lower price than under separation, in order to increase the output of entrants, who respond to the more aggressive pricing by lowering their own prices. The

discussion of this example in Section 4 highlights the importance of this effect. Even in the limit, where the access price a converges to marginal costs c_0 — such that the problem of double marginalization vanishes — legal unbundling leads to strictly higher output than separation. Thus, the downstream expansion effect is in general not only due to the double marginalization problem.

Since one of main policy concerns is about efficient network investments, we extend our analysis to different forms of investment decisions. Given our quantity results, it is quite intuitive that incentives for reducing the upstream firm's marginal costs are highest under legal unbundling. We also consider capacity investments, which can discriminate between downstream firms. For example, foreign producers may be blocked entry into domestic electricity markets when there is no investment into cross-country interconnection capacity. If the total amount of investment is fixed, our previous results carry over and output is maximal under legal unbundling. We cannot exclude cases where the total investment level is higher under separation than under legal unbundling, but we never find investment distortions under legal unbundling that are aimed to protect downstream profits of the incumbent. Finally, we discuss investments into network reliability. To achieve first-best levels of reliability investments, contractual solutions or the imposition of fines in case of network breakdown are generally necessary under all vertical structures. Vertical integration and legal unbundling may have some advantages over separation because they may avoid costly litigation in cases where it is unclear whether the upstream firm or the downstream incumbent was responsible for a network failure.

Despite its great policy relevance in the European Union, there is little literature on legal unbundling. One important exception is Cremer, Crémer, and De Donder (2006). They conceptually introduced the idea to model legal unbundling in the form that the unbundled firm independently maximizes its own profits while being a fully-owned subsidiary. Their approach differs from ours since they assume that the downstream firm is legally unbundled (this is our case of "reverse" unbundling). We focus on the situation where the upstream firm is legally unbundled, which seems to be closer to legal practice where the network operations have to be legally independent. Further differences are that they focus on relation-specific investments but do not consider sabotage; furthermore, in their setup access prices are not set by the regulator, and downstream firms always act as price takers.

In a companion paper, Höffler and Kranz (2007), we analyze the effects of imperfections in legal unbundling. This provides a robustness check for our results

and is briefly reviewed in Section 6.

Apart from this, our paper is related to different strands of literature, namely, in general, to the literature on vertical integration, where an overview is provided, e.g., in Perry (1989). Vickers (1995) is also related, who compares vertical integration with separation under access price regulation and finds mixed welfare results. More recent papers compare investment incentives under vertical integration and separation, like Buehler, Schmutzler, and Benz (2004), who find that generally incentives for quality investments are higher under vertical integration.

Our paper is also related to a literature that focuses on the issue of sabotage; see, e.g., Economides (1998), Beard, Kaserman, and Mayo (2001) or, for an overview, Mandy (2000). Most recently, Mandy and Sappington (2007) compared cost increasing to quality decreasing sabotage in vertical relationships. We analyze a more general setup without restrictions on the downstream firms' cost functions, the strategic variables of downstream competition or the impact of sabotage. We also allow for more general regulatory schemes than linear access pricing and introduce legal unbundling as an alternative ownership structure.

Studying legal unbundling also offers interesting insights into the role of ownership in the theory of the firm. The defining characteristic of ownership can be the right for residual cash-flows (i.e. profits) as in Alchian and Demsetz (1972) or, alternatively, a residual right of control as in Grossman and Hart (1986). Whereas under vertical integration both rights are granted to the incumbent, under legal unbundling ownership entitles to claim residual cash-flows, but grants no (or very limited) residual rights of control.

The remainder of the paper is organized as follows. Section 2 presents the basic model, where we assume a regulated linear access price, and where we derive the basic results. Section 3 examines the different types of upstream investments. Several results are illustrated for the case of price competition with homogenous goods in Section 4, which also includes a complete welfare analysis for this example. In Section 5, we present a general class of regulatory pricing schemes (including two-part tariffs for downstream firms), for which our results hold. Section 6 discusses the results, policy implications, and the effects of imperfect legal unbundling. Section 7 concludes. Unless otherwise stated, all proofs can be found in the appendix.

2 Basic model and results

Structure and Regulation There is a monopolistic upstream firm F_0 that produces a good at constant marginal costs c_0, which is used as input good for n competing downstream firms, $F_1, ..., F_n$. Each downstream firm needs a constant and identical amount of the input good to create an output good. For simplicity, we normalize input quantities such that each firm needs exactly one unit of the input good to create one unit of an output good.

Non-tariff Discrimination We assume F_0 is a regulated natural monopoly, e.g. the owner of an essential transmission network in electricity or telecommunication markets. The regulator fixes a per-unit access price $a > c_0$ that F_0 must charge from all downstream firms (in Section 5, more general pricing schemes are considered). The regulator can enforce the access price but cannot prevent F_0 from hindering some or all downstream firms in some other way. F_0 chooses an action $h \in H$ that specifies some sabotage strategy against downstream firms, like non-disclosure of essential information or undue delays in the provision of ancillary services. Sabotage can increase access costs for certain downstream firms or reduce their demand by creating inconveniences for customers. We assume that the choice of h has no direct impact on the profit of F_0, although perhaps indirectly it does, if it changes the total quantity sold.

Timing First, F_0 chooses its sabotage strategy h. In the extensions of Section 3, F_0 also makes investment decisions. Then, downstream firms engage in downstream competition. An action of downstream firm i is denoted by x_i and $x = (x_1, ..., x_n)$ denotes a profile of actions selected by the downstream firms. Downstream actions can describe a broad range of decisions, for example about quantities, prices, investments, entry or sabotage against competitors.

Unless otherwise stated, we assume that the downstream incumbent F_1 moves first and that $F_2, ..., F_n$ can observe the chosen action x_1. Whether the other downstream firms afterwards move simultaneously or sequentially does not matter for our results. The assumption that the incumbent moves first is mainly for simplicity. We will exemplify that under simultaneous moves still both results hold. We are focusing on subgame perfect equilibria in each of the different games.

Downstream Market and Payoffs Downstream actions, together with sabotage, determine downstream firm i's output $q_i(x, h)$, its market price $p_i(x, h)$ and total costs $C_i(x, h|a)$. Total output quantity is given by $Q(h, x) = \sum_{i=1}^{n} q_i(x, h)$.[8]

---

[8]If firms play mixed strategies, these variables denote expected values. In that case, we

F_0's profits are given by

$$\pi_0(x, h|a) = (a - c_0)Q(x, h) - K + S \tag{1}$$

The constant K represents fixed costs and the constant S possible state subsidies. Note that these upstream profits π_0 are strictly increasing in total output Q. Profits of downstream firm i are given by

$$\pi_i(x, h|a) = p_i(x, h)q_i(x, h) - C_i(x, h|a) \text{ for } i = 1, ..., n \tag{2}$$

Besides a regularity condition that subgame-perfect equilibria exist in every continuation game (Condition C1 below), we make no restrictions on functional forms.

Vertical structures We compare the following four vertical structures.

v : Vertical integration. F_0 and F_1 maximize their joint profits π_{01}, given by

$$\pi_{01} = \pi_1 + \pi_0 \tag{3}$$

s : Vertical separation. All firms maximize their own profits π_i.

u : Legal unbundling: F_0 maximizes its own profits, whereas F_1 maximizes the joint profits π_{01}.

r : Reverse legal unbundling: For comparison reasons we also consider this case where F_0 maximizes joint profits π_{01} and F_1 maximizes its own profits π_1.

The entering downstream firms $i = 2, ..., n$ maximize their own profits π_i under all vertical structures.

Legal unbundling requires that the network part, or more generally, the part of the company controlling the essential facility, has to be separated into a legally independent entity. The EU legislation explicitly states, however, that legal unbundling does not imply that the integrated firm has to sell the network operations. Thus, 100% ownership of the network operations F_0 by the incumbent F_1 is current practice under legal unbundling in many European countries (e.g. in the energy industries in France and Germany).

Legal unbundling in our model is perfect in the sense that we assume that regulators are able to incentivize the management of F_0 such that it maximizes only upstream profits π_0 without considering the incumbent's downstream profits π_1. Arguably, this does not always mirror the actual practice of legal unbundling, although existing legislation explicitly excludes direct instructions of the mother company (Directive 2003/54/EC, Article 10 and 15) or prescribes arm's-length relations (US Telecommunications Act 1996, Section 272 (b) [5]). Furthermore, strict

---

assume that all firms are risk-neutral.

personnel separation, ensuring that professional interests of the upstream firm's employees are separated from downstream interests (e.g. the network unit's managers should not participate in the group's stock option programs), as well as strict monitoring of compliance with those independence requirements are compulsory for 'Independent System Operators' in the new EU proposal for an amendment of Directive 2003/54/EC (issued 2007-09-19). This may help to implement legal unbundling in a way that comes closer to the ideal form assumed in the model. The effects of "imperfect legal unbundling" are discussed in Section 6.

Access prices When we compare the different vertical structures, we consider a given access price a that is the same in every vertical structure. We will perform this comparison for every possible access price $a > c_0$. As we will discuss below, our results are more general than if we had compared only the optimum access price for each vertical structure.

Regularity conditions Since we compare different vertical structures, we essentially compare outcomes of different games. Note, however, that — although payoffs of F_0 and F_1 differ — the timing, the set of players and the strategy space is the same under every vertical structure. To facilitate the comparison of different vertical structures, we introduce two regularity conditions. A *situation* shall describe a vertical structure and a non-terminal history of the multi-stage game, i.e. a history where at least one player still has to move. In order to avoid technical complications that could arise if some continuation games have no subgame-perfect equilibrium, we require:

C1 *In every situation there is a subgame-perfect continuation equilibrium.*

Note that for some forms of downstream competition and sabotage technologies, a given situation can have multiple subgame-perfect continuation equilibria. To simplify comparison between vertical structures in those cases, we also make a regularity condition on equilibrium selection:

C2 *Assume two situations have an identical set of subgame-perfect continuation equilibria. Then in both situations the same subgame-perfect continuation equilibrium shall be selected from this identical set.*[9]

This regularity condition avoids tedious comparison of sets of equilibria. Note that C2 is obviously not needed when, in every situation, there is a unique continuation equilibrium. The following remark summarizes the essential implications

---

[9]Note that there is no conceptual problem in determining whether continuation equilibria under different vertical structures are identical or not, since equilibria are strategy profiles and the strategy space is the same under every vertical structure.

8

of the regularity conditions for the subgame-perfect equilibria in our model:

Remark *Since downstream entrants' profits do depend on h and x, but not directly on the vertical structure, our regularity condition implies that the equilibrium actions of downstream entrants are a function of h and x_1 only. Furthermore, assuming the same sabotage strategy h is chosen under legal unbundling and vertical integration, then downstream firms choose the same equilibrium actions x, since the incumbent maximizes π_{01} under both vertical structures.*

We are now ready to state our first basic result.

Proposition 1 *Under legal unbundling, total output Q and upstream profits π_0 are (weakly) higher than under vertical integration. The result still holds under downstream competition in simultaneous moves.*

Intuitively, total output is higher under legal unbundling than under vertical integration, because vertical integration can cause a *sabotage effect*. Recall from the remark that the outcome under legal unbundling and vertical integration can differ only if F_0's sabotage strategy h differs. (This still holds true if the downstream incumbent moves simultaneously with downstream entrants.) Under legal unbundling, F_0 considers only upstream profits π_0 and therefore chooses h in order to maximize total output Q. This choice can usually be interpreted as performing no sabotage. Under vertical integration, however, F_0 has incentives to sabotage downstream competitors whenever sabotage sufficiently increases the incumbent's downstream profits π_1 — even though the sabotage may decrease upstream profits π_0 and total output Q. We now state our second basic result:

Proposition 2 *Under legal unbundling total output Q and upstream profits π_0 are (weakly) higher than under separation.*

The intuition for Proposition 2 differs from that of Proposition 1. Under both legal unbundling and separation, the upstream firm F_0 wants to maximize total output Q, i.e. there is no sabotage effect. In contrast to separation, under legal unbundling the downstream incumbent F_1 participates in the upstream profits π_0 and therefore has an interest to select a decision x_1 that expands total output Q. We call this the *downstream expansion effect*.

To gain further intuition for the downstream expansion effect, we consider some specific examples of downstream competition. It is helpful to decompose the output expansion under legal unbundling into two parts: the change in the incumbent's own output q_1 and an *induced output effect* that measures the aggregate change in downstream entrants' output.

Consider first the simple case that there are no entrants and F_1 is a downstream monopolist, i.e. there is no induced output effect. Then the output expansion under legal unbundling is due to the intuition known from the double marginalization problem: Under legal unbundling F_1 considers only the true marginal costs c_0 instead of the higher access price a and therefore chooses a higher output than under separation.

In the presence of entrants, the incumbent additionally takes the induced output effect into account. In Section 4, we discuss in detail an example where firms compete in prices. Basically, the incumbent sets an aggressively low price in order to induce higher output by the downstream entrants who match the low price. Even if the access price a converges to the marginal cost c_0, the quantity under legal unbundling is still larger than under vertical separation since—although the double marginalization problem vanishes—the induced output effect is still present.

If firms compete in quantities, a quantity expansion by the incumbent typically induces an output reduction by the entrants. Since the incumbent moves first, he will always take the induced output effect into account and we will thus never find that F_1 takes an action such that total output is lower under legal unbundling than under separation. This means the downstream expansion effect will never be negative when F_1 moves first.

Legal unbundling vs separation under simultaneous moves If the incumbent and entrants move simultaneously, F_1 still prefers higher total output under legal unbundling than under separation. We cannot, however, in general exclude that the incumbent's desire to have higher total output may paradoxically lead to lower total output in equilibrium. Thus the result of Proposition 2 will typically hold only under additional assumptions when downstream firms move simultaneously. An example for this is to consider Cournot competition downstream and to assume a specific sabotage technology: Assume that sabotage linearly increases costs, i.e. $h = \{h_1, ..., h_n\} \in R^n$ such that the cost of firm i become $C_i(h) = (a + h_i) q_i + \widetilde{C}_i(q_i)$ where $\widetilde{C}_i(q_i)$ is just some arbitrary function of q_i. With this assumption, we retain our result of larger quantities under legal unbundling also for the case of simultaneous quantity competition:

Proposition 3 *Consider the special case of the linear sabotage technology. Assume downstream firms compete by simultaneously setting quantities (goods can be differentiated). Then total output is (weakly) higher under legal unbundling than under both separation and vertical integration.*

Under Cournot competition the incumbent does not directly take the induced output effect into account, i.e. its best reply function takes competitors' output as given. The downstream expansion effect is therefore driven by the double marginalization problem: Under legal unbundling, the incumbent calculates with true marginal costs c_0 instead of the higher access price a. Typically, a reduction in one firm's marginal costs will lead to a higher total output in the Cournot equilibrium (see, for example, Farell and Shapiro (1990) for weak regularity conditions for the case of homogeneous goods). The reason that Proposition 3 also holds for cases where total output is increasing in a firm's marginal cost, is that the upstream firm can then prevent output reduction by increasing the incumbent's marginal costs via the linear sabotage technology.

Let us finally discuss simultaneous price competition with differentiated products in the downstream market. Under price competition, the incumbent wants to set lower prices under legal unbundling than under separation, because lower prices increase output. As long as prices are strategic complements, i.e. entrants react to a lower price of the incumbent by lowering their own prices, and total output is weakly decreasing in each firm's price, we find that under legal unbundling no firm sets higher prices and total output is weakly higher than under separation.

Some implications of the output results Our output results suggest that from the consumers' perspective, legal unbundling is likely to be superior to the other two vertical structures. In particular, if the downstream products are homogenous (like, e.g., voice calls, electricity, or gas) and if downstream firms charge linear tariffs, it is immediate that higher quantities yield also a higher consumer surplus.

Corollary 1 *If output goods are perfect substitutes and downstream firms use linear tariffs, consumer surplus is weakly highest under legal unbundling.*

Legal unbundling can also be preferred by taxpayers, since F_0 makes higher profits than under the other vertical structures: if the regulatory regime requires an ex ante subsidy that ensures that F_0 will break even, then such a subsidy would be lowest under legal unbundling.

Corollary 2 *The minimal state subsidy, which guarantees that F_0 makes no losses, is lowest under legal unbundling.*

Total welfare Without assumptions on how discrimination works and how

downstream competition works, results on total welfare are not possible. Clearly there are cases where legal unbundling leads to higher output but to lower welfare, for example if there are sunk costs and legal unbundling facilitates excess entry (see the seminal paper by Mankiw and Whinston (1986)). Nevertheless there will be many cases where total welfare is also highest under legal unbundling. One such case — a homogeneous goods duopoly with price competition — is exemplified in Section 4.

Comparison under optimal access prices Assume consumer surplus (and / or total welfare) is increasing in total output and regulators consider an access price to be optimal if it maximizes total output under the restriction that the upstream firm can recover its fixed costs. In general, the optimal access price can depend on the vertical structure, and one may be interested to compare the total output, under the condition that under each vertical structure the optimal access price is selected. Our results imply that legal unbundling leads to (weakly) higher total output than separation and vertical integration also for the case that such optimal access prices are chosen in every vertical structure. Recall that we have shown that for every access price $a > c_0$ legal unbundling leads to (weakly) higher output than the other vertical structures. Thus even for the access prices that yield the highest output under separation or vertical integration, legal unbundling will lead to (weakly) higher output and (weakly) higher upstream profits. The output difference will even increase if for legal unbundling one would also choose the optimal access price.

Reverse legal unbundling In order to make our results comparable to Cremer, Crémer, and De Donder (2006), what is left to discuss is the case of "reverse unbundling". Recall that reverse legal unbundling means F_0 maximizes π_{01}, whereas F_1 has an independent management and maximizes π_1. In practice, this would imply that e.g. a integrated electricity company would have to form a legally independent sales unit which is owned by the network operations (or by the whole group, including generation facilities). The important point is that with reverse legal unbundling the essential facility would not be separated into an independent unit. We find that reverse unbundling leads to lower quantities in equilibrium compared to vertical separation and, by Proposition 1, also to lower quantities than legal unbundling.

Proposition 4 *Total output Q and upstream profits π_0 under reverse legal unbundling are weakly lower than under separation.*

This finding is different to the results of Cremer, Crémer, and De Donder (2006), because they compare reverse legal unbundling with separation in a model that focuses on relation-specific investments; in this framework, reverse legal unbundling is better suited than separation to overcome the hold-up problem.

3 Investments

3.1 Capacity Investments and Discriminatory Investments

Many types of upstream investments will influence output by downstream firms, e.g. by changing the network capacity. Benefits and impediments from such investments can accrue differently to different downstream firms. For example, investments into interconnection capacity to a foreign country benefit foreign energy producers who want to sell in the domestic market of the network operator.

In the policy debate, there are severe concerns that vertical integration and legal unbundling lead to socially inefficient allocations of such investments, because of overlapping interests of the network operator and the downstream incumbent. The EU Commission states:

> Vertically integrated network operators have no incentive for developing the network in the overall interests of the market and hence for facilitating new entry at generation or supply levels; on the contrary, they have an inherent interest to limit new investment when this will benefit its competitors and bring new competition onto the incumbent's "home market". Instead, the investment decisions made by vertically integrated companies tend to be biased to the needs of supply affiliates. Such companies seem particularly disinclined to increase interconnection or gas import capacity and thereby boosting competition in the incumbent's home market to the detriment of the internal market.[10]

The Commission also makes clear that in its opinion only ownership unbundling, i.e. complete separation, can effectively solve this problem:

> Economic evidence shows that ownership unbundling is the most effective means to ensure choice for energy users and encourage invest-

---

[10]Proposal for amending Directive 2003/54/EC concerning common rules for the internal market in electricity, (issued 2007-09-19), p.5.

ment. This is because separate network companies are not influenced by overlapping supply/generation interests as regards investment decisions.[11]

We will now show, however, that in our model overlapping investment interests are no problem under legal unbundling — although the problem may indeed arise under vertical integration. For the theoretical analysis it is helpful to split F_0's investment decisions into two steps. One step is to decide on the allocation of investment if the total amount that shall be invested is given. The other step is to decide which total amount shall be invested.

We first analyze F_0's allocation decision, assuming that the total amount of investment spending is given. We simply take our basic model and interpret F_0's strategic variable h not only as a sabotage strategy, but also as a decision about the investment allocation, which influences downstream firms' costs and output. This interpretation is completely consistent with our model where downstream firms' output, prices and costs are given by some general functions $q_i(x, h)$, $p_i(x, h)$ and $C_i(x, h|a)$. It is also fulfilled that the allocation of investment has no influence on F_0's costs, because the total amount invested is assumed to be given in this step.

Thus, our output results also apply, i.e., for a given sum of investment, F_0 will under legal unbundling always choose that allocation of investment that maximizes total output and this total output is weakly higher under legal unbundling than under both separation and vertical integration. According to this result, discriminatory allocation of a given sum of investment does not seem to be a problem under legal unbundling.

Examining the second step, we cannot rule out, however, that the total amount of investment is lower under legal unbundling than under the alternative vertical structures and, even more important, that the resulting quantities need not be highest under legal unbundling.

We first illustrate why investments I^s and resulting total output Q^s under separation may exceed the investments I^u and total output Q^u under legal unbundling in some circumstances. Assume that (i) the incumbent is more efficient than the entrants, such that absent an investment, no entrants would be active and (ii) an investment would yield a level playing field for entrants and the incumbent. Under separation and without investment, the double marginalization problem would

---

[11]EU Commission, An Energy Policy for Europe, p. 7, Brussels, 10.1.2007, COM(2007) 1 final.

lead to a quantity lower than under legal unbundling. Thus, investing would yield a large increase in downstream quantities if, due to the investment, we moved from, say, a downstream monopoly to a Bertrand duopoly with identical costs. This increases upstream profits significantly and implies that the investment would be undertaken even if it is relatively costly. With legal unbundling, however, the network unit F_0 might find it optimal not to invest, since it can anticipate that in the quantity decision of the incumbent F_1, the double marginalization problem is internalized and the quantity is relatively large already without an investment.

Although under such special circumstances investments and total output can be lower under legal unbundling, we can establish an upper bound on this output difference $Q^s - Q^u$. It is straightforward to show (see the proof of Proposition 5) that the following inequality holds: $(a - c_0)(Q^s - Q^u) \leq I^s - I^u$. This means that the only reason that F_0 does not make the additional investment under legal unbundling is that the network unit's extra profits from increased network access are lower than the investment costs.

That investments under vertical integration, I^u, can be higher than under legal unbundling, $I^u < I^i$, is less surprising and applies already in quite intuitive examples. Consider an investment that benefits only the incumbent F_1, who might then be able to drive competitors out of the market; this might reduce overall quantity, such that with legal unbundling the network unit F_0 would abstain from such an investment. However, the quantity will typically be higher under legal unbundling. However, it is not possible to generally rule out that vertical separation with discriminatory investments might yield higher quantities than legal unbundling. Again, we can establish the same upper bound for such a theoretically possible output difference; Proposition 5 summarizes our findings:

Proposition 5 *With capacity investments F_0's profits from network operations π_0 minus investment costs are weakly higher under legal unbundling than under both separation and vertical integration. Total output fulfills the following inequalities:*

$$(a - c_0)(Q^s - Q^u) \leq I^s - I^u \ and \ (a - c_0)(Q^v - Q^u) \leq I^v - I^u.$$

Since the output differences $Q^s - Q^u$ and $Q^v - Q^u$ can become large only if the difference in investment costs becomes large, one can conjecture that such "expensive" expansions of downstream quantities are not welfare-enhancing. However, a comprehensive welfare analysis is not possible in our general framework.

Furthermore, the profits of the downstream incumbent play no role in such cases where legal unbundling leads to lower levels of investment and total output.

Thus, even if we find lower output under legal unbundling, this is not related to the EU Commission's fear that the upstream firm would want to protect downstream firm's profits under legal unbundling. The inequality also shows that possible under-investment is (weakly) reduced by increasing the access price a. This might be done in ways that do not distort downstream firms' demand when using the more general regulatory schemes illustrated in Section 5.

3.2   Investments in reducing upstream marginal costs

We now consider a different type of upstream investments, namely process investments of F_0 which reduce its marginal costs c_0 by some amount δ. Investment costs $I(\delta)$ are strictly increasing in the level of marginal costs reduction δ. We first establish the following helpful lemma, which just proves the intuitive idea that for a lower level of upstream marginal costs total output will be weakly higher.

Lemma 1 *Total output under legal unbundling is weakly decreasing in F_0's marginal cost c_0.*

Provided with this intuitive result, we can show that investments and resulting output are highest with legal unbundling.

Proposition 6 *Investment into marginal cost reduction and total output under legal unbundling are weakly higher than under vertical separation and vertical integration.*

This investment result is, of course, mainly driven by the output results of Propositions 1 and 2. When a higher quantity is sold under legal unbundling there are obviously higher gains from cost reduction. Although intuitive, Proposition 6 is not completely trivial, since investments change the output and the extent to which marginal cost reduction increases output can be larger under vertical integration than under legal unbundling. Proposition 6 shows, however, that investments are nevertheless always weakly higher under legal unbundling.

3.3   Investments into network safety and reliability

An important issue for energy and railway networks is safety and reliability. If the network breaks down, severe costs may be inflicted upon the network operator itself, on downstream firms, as well as on final consumers and other on members of society.

Appropriate investments into network reliability are therefore an important issue. Integrated electricity companies sometimes claim that vertical integration is essential to guarantee reliable network operations. One may argue that reliability investments could, indeed, be larger under vertical integration, since not only losses of the network operator but also losses of the own downstream operations are taken into account. However, as long as the losses for the rest of society are not considered, reliability investments will be too low under all vertical structures, including vertical integration.

Sufficient levels of reliability investments therefore require contractual solutions that can impose fines in case of network break-downs or — in cases where contractual solutions are impracticable — fines imposed by the regulator or direct regulation. We do not see a compelling reason why such contractual and regulatory arrangements should be more difficult to achieve under legal unbundling than under the other vertical structures.

Sometimes, however, there may be problems to identify who was responsible for some network failure. Was it a mistake on the part of the upstream firm or on the part of the downstream firm that led to the break-down? In those cases there may be welfare losses due to costly litigation. When F_0 and F_1 are vertically integrated there may be some advantage, because for outsiders it is not important whether the upstream or downstream operations of the integrated firm were responsible for some failure. But also under legal unbundling there should be less costly litigation between F_0 and F_1, since F_1 receives all profits from F_0 and has therefore no interests in a costly law suit.

4   Example: Duopolistic Price Competition

4.1   The case without investments

In the following, we illustrate the output result for a downstream duopoly that sells a homogeneous product, like electricity, and competes in prices (with F_1 moving first), which also allows us to perform a complete welfare analysis. We chose the case of perfectly homogeneous goods, not because we think that the assumption that the downstream firm with the lower price gets the whole market is very realistic. The reason is rather that this extreme assumption leads to a clear example for a downstream expansion effect that is due only to the induced output effect and occurs even in the absence of a problem of double marginalization.

Assumptions There are two downstream firms selling perfect substitutes. Total demand is given by a downward sloping demand function $Q(p)$, $Q'(p) < 0$. We maintain the assumption that the incumbent F_1 moves first. We assume constant marginal cost of the downstream firms, with a cost disadvantage for the incumbent. Sabotage linearly increases downstream costs. Thus, cost functions are given by

$$C_i(q_i) = (c_i + a + h_i) q_i \text{ for } i = 1, 2$$

with $c_1 > c_2$. Considering a cost disadvantage for the incumbent is of interest since a standard argument for liberalizing markets is to allow more efficient firms to enter the downstream market.

To avoid uninteresting case distinctions, we make some regularity conditions. First, we assume that for some prices above the incumbent's marginal cost plus access price $a + c_1$ there is still positive demand, i.e. a separated incumbent could make positive profits if it were a downstream monopolist. Second, we assume that if F_2 were a monopolist on the downstream market, its optimal monopoly price lies above $a + c_1$. Third, we assume that the access price a is not so high that it is Pareto-dominated by some lower access price. This means it is not the case that all firms and consumers would be weakly better off (and at least one of them strictly better off) by some lower access price.

As is well known, in this set-up multiple equilibria can arise. We only consider equilibria in which firms do not play weakly dominated strategies.

Finally, for the question of how the market is split between the two firms in case they choose identical prices, we make the following tie-breaking assumptions. If the price is above F_2's marginal costs, i.e. $p > c_2 + a$, we assume that F_2 gets the whole market (for the out-of-equilibrium event that $p_1 = p_2 < c_2 + a$, we assume F_1 gets the whole market). This captures the idea that if prices were discrete on a sufficiently fine grid then F_2 as second mover would prefer minimally to undercut the price if $p > c_2 + a$ and prefer not to sell any output if $p < c_2 + a$.

If the price is equal to F_2's marginal cost, i.e. $p = c_2 + a$, then F_1 can decide whether F_1 gets the whole market, F_2 gets the whole market, or the market is split equally, i.e. $q_1 = q_2 = \frac{1}{2}Q$. This captures the idea that if prices were discrete, F_1 could either set a price slightly above F_2's marginal cost, in which case F_2 gets the whole market, exactly split the market at F_2's marginal cost, or slightly undercut F_2's marginal cost to get the whole market.

Vertical separation This is the typical Bertrand case, except for the fact that F_1 moves first. We find the following result:

Lemma 2 *Under separation in every equilibrium F_2 gets the whole market. The infimum of the market prices from all equilibria where no firm plays a weakly dominated strategy is given $p = a + c_1$.*

The price $p = a + c_1$, which equals the high cost firm's marginal cost, is the typical Bertrand outcome. Nevertheless there are additional equilibria. As under simultaneous moves, there are equilibria with prices between $a + c_2$ and $a + c_1$, but those are equilibria where F_1 plays a weakly dominated strategy. If there is only a small doubt that F_2 will not undercut F_1, then F_1 will never set a price below its own marginal cost $a + c_1$. Since F_1 moves first and always makes zero profits, there are also equilibria with prices above $a + c_1$, i.e. a price of $a + c_1$ is not the only outcome but the welfare optimal outcome when we neglect weakly dominated strategies.[12]

Legal unbundling Under legal unbundling F_0 again wants to maximize total output and therefore will not sabotage. Contrary to vertical separation, now the downstream incumbent F_1 has an incentive to increase total output, since F_0's profits will accrue to F_1 under legal unbundling. Therefore F_1 will price more aggressively in order to increase output and thereby upstream profits sufficiently. This form of aggressive pricing is taken to the extreme in our case of price competition with homogeneous goods, because here F_1 prices more aggressively without even having some positive market share:

Lemma 3 *Under legal unbundling F_0 sets $h_2 = 0$. F_1 and F_2 both set prices $c_2 + a$ and F_2 gets the whole market.*

Note that even though the price set by F_1, $p_1 = a + c_2$, can be below F_1's true marginal costs $c_0 + c_1$, it is not a weakly dominated strategy for F_1 to set such a price — in contrast to what we found under vertical separation. This is because if F_1 would set a higher price, F_2 would react with a higher price and total output, and therefore the profit of the integrated firm $\pi_0 + \pi_1$ would be reduced.

Vertical integration With vertical integration, there are two candidates for an equilibrium. Either the upstream firm uses sabotage in order to drive F_2 out of the market (the "monopolistic" outcome), or F_0 does not sabotage F_2 and then F_1 acts in the same way as under legal unbundling (the "competitive" outcome).

---

[12]To be precise, in the equilibrium with a price of exactly $a + c_1$, F_1 also plays a weakly dominated strategy since for no action of F_2 will F_1 make positive profits. But there is a sequence of equilibrium prices that converges from above to $a + c_1$, where in no such equilibrium a firm plays a weakly dominated strategy.

Lemma 4 *If F_0 and F_1 are integrated. There are two candidates for equilibrium:*
(m) monopoly case: Set $h_2 = \infty$ and let F_1 serve the whole market at the monopoly price of the integrated firm p_{10}^m.
(u) competitive case: The same as under legal unbundling. Set $h_2 = 0$ and $p_1 = p_2 = c_2 + a$ and let F_2 get the whole market.

In the monopoly case profits of the integrated firm are given by

$$\pi_{01}^m = (p_{01}^m - c_0 - c_1) \, Q \, (p_{01}^m)$$

In the competitive case its profits are given by

$$\pi_{01}^u = (a - c_0) Q(c_2 + a)$$

We find $\frac{\partial \left(\pi_{01}^u - \pi_{01}^m \right)}{\partial c_1} > 0$ and $\frac{\partial \left(\pi_{01}^u - \pi_{01}^m \right)}{\partial c_2} < 0$. This means the competitive outcome occurs whenever the cost disadvantage of the own downstream operations is sufficiently large. With very inefficient own downstream operations, even the integrated firm might find it optimal to use F_2 as its "sales channel" and live only on the upstream profits. In this case, clearly, sabotage would not make sense.

Reverse legal unbundling The following lemma shows that under reverse legal unbundling we either have the same market price as under separation or the monopoly price of an integrated firm. In fact, the worse of these two outcomes is realized, i.e. reverse legal unbundling is weakly worse than both separation and vertical integration.

Lemma 5 *Under reverse legal unbundling the market price will be $p = \max\{p_{10}^m, a + c_1\}$. At price $a + c_1$ firms F_1 or F_2 may produce, but at price p_{10}^m, F_1 will serve the whole market.*

The intuition is that under reverse legal unbundling, F_0 maximizes joint profits and therefore has incentives for sabotage, and at the same time F_1 only maximizes its own profits and therefore has no incentives to lower prices in order to increase output.

Comparison of the four cases Equipped with the solutions for the four cases we see that in this example legal unbundling is strictly superior to all other vertical structures (except for the competitive case of vertical integration, which yields an outcome identical to legal unbundling). Total output and consumer surplus are inversely related to the market price and therefore highest under legal unbundling. Profits of F_0 are increasing in total output and hence also highest under legal

unbundling. Production is efficient since F_2 produces everything. Total welfare is increasing in total output as long as market prices are weakly above marginal cost of production $c_0 + c_2$, which is always the case. Thus we can state the following proposition:

Proposition 7 *Under legal unbundling, prices are strictly lower, and total output, profit of F_0, consumer surplus and total welfare are strictly higher than under separation, reverse legal unbundling and the monopoly case of vertical integration. (In the competitive case of vertical integration, we have identical outcomes to legal unbundling).*

Proof. Immediate from comparing the outcomes of the four cases. ■

One reason for welfare losses is that we assumed imperfect upstream regulation, i.e. the access price a is above the marginal cost of producing access, $a > c_0$. Especially from a theoretical perspective, it is therefore interesting to investigate what would happen if regulation improved in the sense that a approaches the true cost of access c_0. Only for legal unbundling the outcome will approach the first best, i.e. the final market price will equal $p^{FB} = c_0 + c_2$. For separation as well as for integration, the market outcome remains inefficient even for $a = c_0$. With separation, the market price converges to $p = c_0 + c_1 > p^{FB}$, due to the assumption $c_1 > c_2$. And for vertical integration we find that for $a \to c_0$, the monopoly case always arises since income from selling input goods $(a - c_0)Q$ converges to zero.

Proposition 8 *With perfect upstream regulation, $a \to c_0$, legal unbundling obtains the first best while the other vertical structures do not converge to the first best.*

Proof. Immediate from comparing the outcomes of the four cases. ■

This result also nicely illustrates that the welfare advantage of legal unbundling over separation is not only due to the reduction of a double marginalization problem. In the limit $a \to c_0$ the double marginalization problem vanishes, but nevertheless legal unbundling performs strictly better than separation.

4.2   Investment into marginal cost reduction

We also want to illustrate, for our example, investment decisions into marginal cost reduction. Assume F_0 can reduce marginal costs by some amount $\delta < c_0$ where cost reduction requires investments of $I(\delta)$, with $I'(\delta) > 0$ and $I''(\delta) > 0$.

Let I^u, I^v, I^s denote the investment levels chosen by F_0 under the different vertical structures. We compare these investment levels to the levels a social planner would choose, under the restriction that the price of access is a and that downstream competition is not regulated (this reflects the idea that a regulator believes that a is set correctly, i.e. we neglect the inefficiencies stemming from imperfect upstream regulation and the lack of downstream regulation). We denote by I_o^u, I_o^v and I_o^s these (second best) socially optimal investment levels under legal unbundling, vertical integration and separation, respectively. We find:

Proposition 9 *Under both legal unbundling and vertical separation F_0 will select the socially optimal level of investment, i.e. $I^u = I_o^u$ and $I^s = I_o^s$. Investment incentives under vertical integration can be inefficient, however.*

In our example a change in marginal costs c_0 has no effect on the total output size Q under both legal unbundling and separation. Thus, the social marginal gain as well as F_0's marginal gain from reducing c_0 are both given by Q. Hence, F_0's interests are perfectly aligned with those of society as a whole.

With vertical integration, on the other hand, the investment incentives are more complex since changes in c_0 change the optimal downstream price p_{01}^m, and therefore the output.

5   Alternative regulatory pricing schemes

5.1   A general class of price regulation schemes where legal unbundling is optimal

So far we assumed that the regulator sets a linear access price $a > c_0$. Such linear access prices fulfill two conditions:

(L1) F_0's profits π_0 only depend on total output Q, but it does not matter which downstream firms produce how much of it.

(L2) F_0's profits π_0 are strictly increasing in total output Q.

It turns out that our main results hold for every price regulation scheme that fulfills conditions (L1) and (L2). Let α denote a price regulation scheme that fulfills (L1) and (L2). It determines how much money F_0 receives when selling a total output Q, which we denote by a revenue function $R(Q|\alpha)$. Furthermore the

scheme α specifies how much downstream firms have to pay when actions x are chosen (which imply quantities q_i). Thus profits are given by

$$\pi_0(x, h|\alpha) = R(Q(x, h)|\alpha) - c_0 Q(x, h) - K + S$$

$$\pi_i(x, h|\alpha) = p_i(x, h)q_i(x, h) - C_i(x, h|\alpha) \text{ for } i = 1, ..., n$$

To ensure that (L2) is fulfilled, we require that for all Q', Q with $Q' > Q$ it holds that $R(Q'|\alpha) - c_0 Q' > R(Q|a) - c_0 Q$.

Consider the following example for such a pricing scheme: The regulator pays the upstream firm a linear access price $a > c_0$, but charges the downstream firms a two-part tariff with an access price equal to c_0 plus a fixed fee. It is not necessary that the regulators' revenues have to equal expenditures, i.e. the higher marginal price paid to F_0 may also be partly financed by subsidies. This scheme has two benefits: First, a high access price a gives F_0 strong incentives to maximize total output, which may be a good way to induce a sufficient high budget for capacity investments (see Section 3.1). Second, output in downstream markets is increased because, for the downstream firms, access is priced at its true marginal costs c_0. Even though under this scheme there is no double marginalization problem, output under legal unbundling may still be *strictly* above the output under separation, by essentially the same intuition we gained from the induced output effect in the price competition example where the linear access price a converged against marginal costs c_0.

For these more general regulatory schemes, which provide scope for additional desirable features, all the results proven in Section 3 and 4 still hold.

Proposition 10 *The following results hold for every regulatory pricing scheme that fulfills (L1) and (L2): Proposition 1, 2, 4, 5 (first sentence) and 6.*

Our proofs for the mentioned propositions in the appendix all use the more general class of regulatory schemes illustrated in this section. Thus, we find that also for the larger class of regulatory schemes, legal unbundling can be seen as a golden mean between separation and vertical integration as it still delivers higher quantities and better investment incentives.

5.2 Inappropriateness of legal unbundling in the absence of access regulation

It is important to note that legal unbundling can yield very bad outcomes if access prices are unregulated. If F_0 could freely decide on access prices, the strategy

that maximizes upstream profits π_0 would be to charge the incumbent F_1 a very high access price and at the same time use all available measures to maximize F_1's output, which could involve massive sabotage of downstream competitors. F_1 is willing to pay such a high access price, because it gets the money back through F_0's profits. Although in reality this mechanism will likely not appear in this extreme way, the basic incentive distortions are nevertheless likely to exist without price regulation. Along the lines of this example, an apparently harmless rule that only prescribes a maximum access price for downstream competitors, but allows (or requires) higher access prices for the downstream incumbent may have quite negative outcomes. Thus whenever there is no access price regulation or the conditions (L1) and (L2) from above are violated, legal unbundling may lose its appealing properties.

6   Discussion

The analysis so far has shown that under rather general assumptions, legal unbundling exhibits desirable properties. Nevertheless, regulatory authorities often evaluate legal unbundling negatively. For instance, Neelie Kroes, European Competition Commissioner, expressed her views as follows:

> Speaking very personally, I see only one way forward if we are to restore credibility and faith in the market. Europe has had enough of "Chinese walls" and quasiindependence. There has to be a structural solution that once and for all separates infrastructure from supply and generation. In other words: ownership unbundling.[13]

A key concern in the European policy debate on vertical industry structures are investment incentives, in particular, for investments in cross-border transmission capacities. Such investments could pave the way for an integrated European market for electricity with an increased level of competition. Also for this issue, the EU Commission prefers vertical separation over legal unbundling. In the words of Commissioner Kroes:

> As you will know, where interconnector capacity is scarce, it is auctioned off to the highest bidder, generating congestion revenues.

---

[13]Speech Neelie Kroes, A new energy policy for a new era, Conference on European Energy Strategy – the Geopolitical Challenges, Lisbon, 30th October 2006.

If you look at our report, you will find that from 2001 to 2005, three German TSOs generated congestion revenues of over 400 million Euros. Of these revenues, under 30 million Euros were used to build new interconnectors- that's less than 10%!

In contrast, our experience shows that fully unbundled operators see clearer incentives for investment in interconnectivity, and act on those incentives, because they are focused on optimizing the use of the network.[14]

Although the European Commission views vertical separation (or ownership unbundling) as the most preferred vertical industry structure, it has positively considered an alternative structure with an "independent systems operator":

[...] the Commission has also examined an alternative approach known as 'ISO' or Independent System Operator, whereby the vertically integrated company maintains ownership of the network assets and receives a regulated return on them, but is not responsible for their operation, maintenance or development.[15]

We believe that our analysis helps to understand better the effects from measures mentioned in the three quotes. We discuss the three points in turn.

First, our theoretical analysis assumed that legal unbundling works perfectly in separating the interests of the network company from the rest of the integrated group. This seems often not to be the case. Thus, it is important to understand what happens if the network company acts not completely independently and also takes into account the profits of the downstream firm F_1. This is analyzed in detail in Höffler and Kranz (2007). There it is shown that reducing the independence of the network firm yields the expected result of lowering total output. Put differently: more independence, i.e. a stronger regulation, increases the output. The optimum ownership structure therefore can depend on the strength of regulation. Höffler and Kranz (2007) show that if regulation is weak, vertical separation can indeed yield higher quantities than legal unbundling. However, if regulation is

_____

[14]Neelie Kroes, European Commissioner for Competition Policy, 'A new European Energy Policy; reaping the benefits of open and competitive markets' Energy conference: E-world energy & water' Essen, 5th February 2007

[15]Neelie Kroes European Commissioner for Competition Policy 'A new European Energy Policy; reaping the benefits of open and competitive markets' Energy conference: E-world energy & water' Essen, 5th February 2007.

sufficiently strong, the results of the current paper apply (i.e. highest quantities under legal unbundling).

Since the effect of legal unbundling therefore seems to depend on the strength of regulation, the negative experiences of regulators may well be explained by insufficiently strong regulation. Although "sufficiently strong" regulation might not be implementable as such,[16] it might also be the case that intensifying regulation is possible and that such a strengthening of regulation will lead to a situation where legal unbundling is the preferred vertical structure. This could be done either by stronger legal requirements or by stricter implementation of existing rules. The second quote illustrates the point. Only since 2005 have German network companies been legally obliged to reinvest profits from the interconnector auctions[17] — thus, legal requirements have become more strict (irrespective of the question whether this particular tightening of regulation is sensible — below we propose an alternative approach to this problem). If the integrated companies still get away with not reinvesting, this would be due to a lack of enforcement of legal rules. The European Commission itself states that the existing rules are not yet fully implemented.[18] Thus, too little independence might at least partially be due to too weak implementation of existing regulation.

The resulting policy implication, therefore, is to strengthen regulation and to thoroughly implement the existing regulations in order to increase the independence before changing the regime towards full separation. Additionally, requiring legally unbundled firms to take on a minority outside investor, could help to increase independence. Consider a minority stake of, say 10%, of an institutional investor in the network company. The interest of the downstream firm in the network profits would still be large, such that beneficial effects of legal unbundling are still significant; at the same time, the investor has an interest in enforcing that the network company maximizes only its own profits.

---

[16] Although many legal rules exist to ensure independence (mentioned in section two), reaching perfect independence might nevertheless be difficult. For instance, even if the management of the network company today has no incentive to privilege the incumbent's downstream operations, career concerns within the group might bias decisions towards such a discriminatory behavior.

[17] In Germany, according to the *Netzzugangsverordnung* § 15 (3).

[18] That legal unbundling requirements are not yet fully implemented is explicitly noticed by the European Commission: "Even where Member States have adopted unbundling provisions required under the Second Gas Directive, this does not mean that TSOs necessarily comply with them." (Sector Inquiry, Part 1, para 153, p. 57).

The issue of investments, addressed in the second quote, is also interesting in light of our findings. From a theoretical perspective, completely separated network operators will also have incentives to provide only a monopoly amount of interconnector capacity — below the socially optimal level — if they directly receive the congestion revenues from the interconnector auctions.[19] Theory can also predict that legal unbundling can exaggerate this problem, since under legal unbundling the downstream incumbent may bid higher prices in the capacity auction in order to increase congestion revenues and thereby the profits of the network operator.

In this context, our discussion of more general regulatory schemes proves useful. One suggestion is to modify the capacity auction as follows: The regulator receives the revenues from the capacity auction and pays the network operator a regulated fixed access price for every unit that is sold in the auction. Then the network operator cannot influence the price it receives and therefore has no incentives to act like a capacity-reducing monopolist. Such a regime satisfies the assumptions of section 5.1; thus, we expect that legal unbundling will yield a higher output than separation under this modified regulation scheme.

Finally, consider the issue of independent system operators, subject to a rate of return regulation, mentioned in the third quote. The driving force for the benefits of legal unbundling over separation in our model is the fact that the downstream incumbent receives the network operator's profits and therefore wants to increase total output. But if, as suggested, the downstream incumbent only receives a regulated return on its network assets (independent of the profits from network operations), it has no incentive to increase total output, and the benefits of legal unbundling compared to separation would not arise.

To conclude the discussion, let us remark that we have left out some important issues. For instance, we have not discussed "vertical economies", i.e. possible efficiency gains from vertical integration from a technological or transaction cost point of view. The evidence for their existence is somewhat unclear, however. Fraquelli, Piacenza, and Vannoni (2005), Kwoka (2002), or Kaserman and Mayo (1991), for example, find evidence for more or less economically significant vertical economies. Although such economies of vertical integration may not be fully realized under legal unbundling, they should be realized to a larger extent than under complete separation. For example, the hold-up problem is likely to be reduced under legal unbundling, since F_1 would in an investment decision take

---

[19]See Höffler and Wittmann (2007) for a discussion of "supply reduction" in interconnector auctions.

into account the surplus accruing to F_0 and also has no interest in costly ex-post bargaining with F_0.

7   Conclusion

In this paper, we have demonstrated that, from a theoretical point, legal unbundling can be seen as a "golden mean" between complete separation and full vertical integration. If legal unbundling can ensure that the network company, controlling the essential facility, maximizes only the own profits, legal unbundling ensures higher quantities and better incentives for investments in upstream process innovations and the allocation of capacity investments. We also analyzed the impact on the size of capacity investments; here, we found that legal unbundling does not always lead to highest levels of investments or total output, but also illustrated that lower levels of investment and output do not imply that total welfare is lower under legal unbundling in those cases. Concerning investments into network reliability, we argued that contractual solutions or appropriate regulation are needed under all vertical structures to ensure sufficient levels of investment.

We demonstrated that our results also apply not only for linear access prices, but also for more general regulatory regimes. The characterization of the larger class of regulatory schemes pointed out that the right upstream regulation is crucial for legal unbundling to be beneficial.

Policy recommendations cannot ignore the negative experiences regulators have made so far with legal unbundling. Our contribution is to offer a fairly general economic analysis of legal unbundling which helps to see potential benefits and to identify the necessary prerequisites for these benefits to apply. Our tentative policy recommendation would therefore be: Regulators should first try to implement legal unbundling rigorously, with particular emphasis on the independent decision making in the unbundled network unit, considering also to oblige legally unbundled network operators to take on minority shareholders. Only if experiences after full implementation are still negative, a regime shift towards full vertical separation should be considered.

Appendix: Proofs

We prove Propositions 1, 3, 4 (first sentence), 5, 6 and Lemma 1 and 2 directly for the more general regulatory schemes introduced in section 5. The original propositions are a special case of this set-up, since a linear access price $a > c_0$ fulfills conditions (L1) and (L2). We will generally use the notation Q^u, Q^v and Q^s to denote the resulting outputs, under legal unbundling, vertical integration and separation, respectively and similarly h^u, h^v, h^s and x^u, x^v, x^s for firms' equilibrium choices in the different vertical structures.

Proof of Proposition 1: Under legal unbundling, F_0 sets h in order to maximize upstream profits π_0, and by choosing the same sabotage strategy than under vertical integration, F_0 can guarantee the same level of upstream profits — recall from the remark before Proposition 1 that the outcome under both structures will be the same whenever the sabotage strategy h is the same, even if downstream firms move simultaneously. Since π_0 is strictly increasing in total output Q and vice versa, also total output under legal unbundling is always as least as high as under vertical integration.

Proof of Proposition 2: We show that F_0 can guarantee a weakly higher total output under legal unbundling than under separation, i.e. $Q^u \geq Q^s$ by choosing under legal unbundling the same sabotage strategy than the optimal sabotage strategy h^s under separation, i.e. by setting $h^u = h^s$. Under full separation, the incumbent F_1 then chooses x^s to maximize $\pi_1(x, h^s)$, and under legal unbundling F_1 chooses x^u to maximize $\pi_1(x, h^s) + \pi_0(x, h^s)$. Optimal choice by F_1 thus implies

$$\pi_1(x^s, h^s) \geq \pi_1(x^u, h^s)$$

$$\pi_1(x^u, h^s) + \pi_0(x^u, h^s) \geq \pi_1(x^s, h^s) + \pi_0(x^s, h^s)$$

Adding both inequalities yields $\pi_0(x^u, h^s) \geq \pi_0(x^s, h^s)$ and since upstream profits π_0 are strictly increasing in total output, this implies that total output is weakly higher under legal unbundling than under separation, i.e. $Q(x^u, h^s) \geq Q(x^s, h^s)$.∎

Proof of Proposition 3: (Cournot) F_0 can guarantee the same output under legal unbundling than under separation, an output of $Q^u = Q^s$, by setting $h_1^u = h_1^s + (a - c_0)$ and hampering all other entrants in the same way as under vertical separation, i.e. setting $h_i^u = h_i^s$ for all $i = 2, ..., n$. With such hampering F_1 maximizes under legal unbundling

$$\pi_1^s(q) + (a - c)q_2.$$

where $\pi_1^s(q)$ denotes F_1's profit function under vertical separation. The added term $(a - c)q_2$ has no influence on F_1's best reply function and therefore both firms have the same best reply functions as under vertical separation, leading to the same equilibrium outcome.■

Proof of Proposition 4: If F_0 sets the same sabotage strategy under separation than under reverse legal unbundling, i.e. $h^s = h^r$ the total output and π_0 will be the same, since downstream firms will act in the same way. Since under separation F_0 wants to maximize total output and π_0, it will at least achieve output and π_0 at least as high as under reverse legal unbundling, which is guaranteed by setting $h^s = h^r$.■

Proof of Proposition 5: If under legal unbundling the same total amount would be invested as under separation (vertical integration), we only have an investment allocation problem, which is equivalent to our basic model as explained in the text. Thus, Proposition 1 applies and we know that π_0 must be weakly higher under legal unbundling. F_0 chooses a different investment level under legal unbundling than the optimal level under separation (vertical integration), only if this would lead to even larger net profits $\pi_0 - I^u$. Therefore the first sentence is true. The second sentence follows directly from the first result, under a linear access price $a > c_0$, by inserting π_0 and rearranging the inequalities.■

Proof of Lemma 1: Let c_0^a and c_0^b be two marginal costs with $c_0^a > c_0^b$. Let h^a denote F_0's optimal h if marginal costs are c_a, and let x^a be the selected downstream equilibrium given h^a and c_a. We define h^a and x^b correspondingly. Under legal unbundling F_0 wants to maximize total output Q. We show that F_0 can guarantee $Q^b \geq Q^a$ by setting $h^b = h^a$. Optimal choice by F_1 then implies

$$\pi_1(x^a, h^a) + R\left(Q(x^a, h^a)\right) - c_0^a Q(x^a, h^a) \geq \pi_1(x^b, h^a) + R\left(Q(x^b, h^a)\right) - c_0^a Q(x^b, h^a)$$
$$\pi_1(x^b, h^a) + R\left(Q(x^b, h^a)\right) - c_0^b Q(x^b, h^a) \geq \pi_1(x^a, h^a) + R\left(Q(x^a, h^a)\right) - c_0^b Q(x^a, h^a)$$

Adding up the two inequalities yields $(c_0^a - c_0^b)Q(x^b, h^a) \geq (c_0^a - c_0^b)Q(x^a, h^a)$ and therefore $Q(x^b, h^a) \geq Q(x^a, h^a)$.■

Proof of Proposition 6: Let I_a and I_b be two investment levels with $I_a < I_b$ and let c_0^a and c_0^b with $c_0^a > c_0^b$ be the resulting marginal costs. Generally subscripts or superscripts a and b index the investment level that is considered, while u, v and s index in the vertical structure in the common way. Let $\Delta_{ab}^u := \pi_0^b(h_b^u, x_b^u) - \pi_0^a(h_a^u, x_a^u)$, $\Delta_{ab}^s := \pi_0^b(h_b^s, x_b^s) - \pi_0^a(h_a^s, x_a^s)$ and $\Delta_{ab}^v := \pi_{01}^b(h_b^v, x_b^v) - \pi_{01}^a(h_a^v, x_a^v)$ denote the changes in F_0's objective function when marginal costs change from c_a to c_b (excluding the change in investment costs $I_b - I_a$) under the different vertical

structures.

We will first derive a lower bound on Δ_{ab}^u. Recall that π_0 is strictly increasing in total output. Therefore $Q(h_b^u, x_b^u)$ is the highest quantity that F_0 can achieve with marginal costs c_0^b and by Lemma 1 also no higher quantity can be achieved under marginal costs c_0^a. Therefore $\pi_0^a(h_a^u, x_a^u) \leq \pi_0^a(h_b^u, x_b^u)$. Furthermore, $\pi_0^b(h_b^u, x_b^u) - \pi_0^a(x_b^u, h_b^u) = \left(c_0^a - c_0^b\right)(Q(h_b^u, x_b^u))$. Together with the definition of Δ_{ab}^u, these two results imply

$$\Delta_{ab}^u \geq \left(c_0^a - c_0^b\right) Q(h_b^u, x_b^u).$$

We will now show that $\Delta_{ab}^u - \Delta_{ab}^s \geq 0$ and $\Delta_{ab}^u - \Delta_{ab}^v \geq 0$, which implies that under legal unbundling we will always find weakly higher investment than under separation as well as integration.

(i) $\Delta_{ab}^u - \Delta_{ab}^s \geq 0$: Under complete separation, the total quantity Q^s is independent of F_0's cost structure. Thus moving from c_a to c_b changes F_0's profits by

$$\Delta_{ab}^s = \left(c_0^a - c_0^b\right) Q^s.$$

By Proposition 1, $Q_b^u \geq Q^s$ and using the lower bound on Δ_{ab}^u we find

$$\Delta_{ab}^u - \Delta_{ab}^s \geq \left(c_0^a - c_0^b\right)(Q_b^u - Q^s) \geq 0.$$

(ii) $\Delta_{ab}^u - \Delta_{ab}^s \geq 0$: Since under vertical integration both F_0 and F_1 want to maximize π_{01}, we have $\pi_{01}^a(h_a^v, x_a^v) \geq \pi_{01}^a(h_b^v, x_b^v)$. Furthermore, $\pi_{01}^b(h_b^v, x_b^v) - \pi_{01}^a(h_b^v, x_b^v) = \left(c_0^a - c_0^b\right) Q(h_b^v, x_b^v)$. Together with the definition of Δ_{ab}^v, these two results imply $\Delta_{ab}^v \leq \left(c_0^a - c_0^b\right) Q(h_b^v, x_b^v)$. By Proposition 1, we have $Q(h_b^u, x_b^u) \geq Q(h_b^v, x_b^v)$ and using the lower bound on Δ_{ab}^u, we therefore find $\Delta_{ab}^u - \Delta_{ab}^v \geq \left(c_0^a - c_0^b\right)(Q_b^u - Q_b^v) \geq 0$.∎

Proof of Lemma 2: Standard case of price competition, see derivation in Section 4.

Proof of Lemma 3: At price $c_2 + a$ the incumbent F_1 prefers to give the whole market to F_2, since π_1 is strictly negative for all prices below $c_1 + a$. F_0 can guarantee this outcome by not sabotaging F_2, and therefore no equilibrium with a higher price than $c_2 + a$ can exist. If a is large there could be cases, however, with an equilibrium price p' strictly between $c_0 + c_1$ and $c_2 + a$ where F_1 gets the whole market. Although π_1 would then be negative, joint profits $\pi_1 + \pi_0$ could be higher than under the outcome where F_2 gets the whole market at price $c_2 + a$, because output Q and upstream profits π_0 are higher. Such an equilibrium with a price $p' < c_2 + a$ can only arise, however, if the access price is Pareto-dominated

31

by a lower access price. To see this, consider an access price $a' < a$ that fulfills $a' + c_2 = p'$. With such an access price, F_1 would prefer to give the whole market to F_2 at price p' instead of taking the market itself (since π_1 is negative under p'). Access price a' Pareto-dominates access price a, because no firm nor consumers are worse off and F_1 is strictly better off under this outcome with access price a'.■

Proof of Lemma 4: If F_1 gets the market, then the optimal price is F_1's monopoly price under costs $c_1 + c_0$. If F_2 gets the total market it is optimal that this happens at the lowest possible price that F_2 is ever willing to pay, i.e. $c_2 + a$. Joint profit π_{01} can also not be higher in a situation where both firms split total output at some price p. Since goods are perfect substitutes and marginal costs linear, π_{01} from splitting the market is at least as high if either only F_1 or only F_2 gets the total market at the same price p.■

Proof of Lemma 5: Since under reverse legal unbundling F_1 maximizes its own profits π_1 and by assumption plays no weakly dominated strategy, F_1 will never set a price below $a + c_1$, which implies that no equilibrium with a price below $a + c_1$ exists. Since F_0 maximizes joint profits $\pi_0 + \pi_1$ and π_1 is non-negative for all prices $p \geq a + c_1$, F_0 weakly prefers that F_1 serves the whole market. Joint profit π_{01} is then maximized by the monopoly price would be p_{10}^m. If $a + c_1 \leq p_{10}^m$, then F_0 can achieve this outcome by setting h_2 such that $a + c_2 + h_2 = p_{10}^m$. Then F_1 will a price equal to p_{10}^m and get the whole market. If $a + c_1 > p_{10}^m$ the from all prices achievable in equilibrium the price $p = a + c_1$ maximize π_{01}. This can be achieved by F_0 setting h_2 such that $a + c_2 + h_2 = a + c_1$. Whether F_1 or F_2 gets the market in this equilibrium does not matter.■

Proof of Proposition 9: We prove the first sentence of the proposition for the case of legal unbundling; for vertical separation, the steps are similar. Total welfare, excluding investment costs, under legal unbundling is in our Bertrand model given by

$$W^u = CS(p^u) + p^u Q(p^u) - (c_0 - \delta + c_2) Q(p^u)$$

where the market price $p^u = a + c_2$ does not depend on c_0 and δ. We thus find $\frac{\partial W^u}{\partial \delta} = Q^u$ and $\frac{\partial^2 W^u}{\partial \delta^2} = 0$. Maximization of $W^u(\delta) - I(\delta)$ is therefore equivalent to the first order condition

$$I'(\delta_u^o) = Q^u.$$

F_0 will choose its actual level of cost reduction δ_u in order to maximize its profit $(a - c_0 + \delta) Q(p^u) - I(\delta)$. The profit-maximizing δ_u fulfills the same first order

condition than δ_u^o, i.e.

$$I'(\delta_u) = Q^u.$$

Therefore $\delta_u = \delta_u^o$ and $I_u = I(\delta_u) = I(\delta_u^o) = I_u^o$.

The proof of the second sentence is by use of an example. Let $Q(p) = 1 - p$ and $I(\delta) = \frac{3}{4}\delta^2$ such that $I'(\delta) = \frac{6}{4}\delta$. Let $c_1 = 0.3$, $c_2 = 0.25$, $c_0 = 0.5$ an $a = 0.74$. Then for all δ the monopoly case will be selected under vertical integration since, $1 - 0.8 + \delta - 2\sqrt{(0.24 + \delta)(0.01)} \geq 0$ for all $\delta > 0$. We will get $\delta_m^o = 0.2$ and $\delta_m = 0.1$. As well as $\frac{I_m^o}{I_m} = 4$. This means the optimal investment would be 4 times higher than the actual investment under vertical integration.∎
