Contests Among Bureaucrats

Dieter Bös*

Department of Economics, University of Bonn, D-53113 Bonn, Germany

Abstract

This paper deals with double lobbying: several bureaucrats participate in joint lobbying to get a high total departmental budget, but they also engage in antagonistic lobbying to reap as high a share of the total budget as possible. The antagonistic lobbying constitutes a contest among the bureaucrats. This paper characterizes the Nash equilibria in lobbying and shows in which way exogenously fixed bureaucratic incomes induce the same or different lobbying behavior as incentive incomes.

Keywords: Bureaucracy, Lobbying, Contests

1 Introduction

The trade-off between joint interests and antagonistic interests is a general phenomenon which can often be observed in political economics. It is particularly relevant whenever a group of economic agents unites their efforts in order to receive a large amount of money for the total group, but also splits their efforts because every individual agent wants to get a high personal share of the total money. In this paper we consider various bureaucrats who are part of a department. They share a total departmental budget which is appropriated by a sponsor, be it the parliament or a minister. Every single bureaucrat wants to administrate an individual budget that is as high as possible. A high individual budget results if a bureaucrat gets a high share of a high departmental budget. Therefore, all bureaucrats together participate in *joint lobbying* to get a high departmental budget. However, every bureaucrat will also engage in *antagonistic lobbying* against his co-bureaucrats in order to induce the sponsor to appropriate a high individual budget to his personal bureau. Antagonistic lobbying constitutes a contest among bureaucrats.

There are many examples which can be used to illustrate the interplay between joint and antagonistic lobbying in economic practice. Consider the usual process of budgeting. National defense, for instance, is awarded a total sum of money by the parliament. All generals unite in joint lobbying to attain a high defense budget. But, of course, the army, the navy, and the air force will engage in antagonistic lobbying to increase their individual sub-budgets. Alternatively, think of a group of scientific researchers who apply for a total grant which is split among the various professors. The interest in a high total budget will induce joint lobbying efforts, the interest in a high personal share in this budget will induce antagonistic lobbying. Finally, consider problems of fiscal federalism, where states get fiscal grants from the federal government. All states will unite in joint lobbying to reap a high share of all taxpayers' money for the group of the states. However, at the same time, antagonistic lobbying takes place, because every state will want to increase its share at the expense of the other states.

To capture the essentials of the particular trade-off between joint and antagonistic lobbying we set up a contest model which on the one hand builds on the tradition of rent-seeking models, but on the other hand exhibits special features which have not yet been addressed in the literature on lobbying.

(i) The bureaucrats do not engage in a winner-take-it-all contest, they compete for a share of a divisible budget and not for the whole of an indivisible budget. This is in contrast to much of the literature on rent-seeking contests as, for instance, Tullock

(1980, 1984), Hillman and Katz (1984), Hillman and Samet (1987) and Ursprung (1990).

(ii) The bureaucrat's lobbying efforts influence both their share in the budget and the total budget. This feature, in itself, is not new. In Chung (1996), Hausken (1995a,b, 2000), and Van Long and Vousden (1987: section II) each individual's lobbying effort benefits the agents by increasing the share of the prize they get (a private good) *and* by increasing the total prize to be allocated to the agents (a public good). So the core of these models is a twofold positive effect of the individual lobbying efforts. However, while there are many cases where this assumption is meaningful (see the examples in Chung, 1996: 56-57), the above specification does not cope with the special cases mentioned in the beginning of the introduction to this paper. These special cases cannot be characterized by the interplay of two positive effects of individual lobbying. Rather, we have a positive and a negative effect: the amount of effort spent to reap a larger share of the budget is lost for the joint effort which is needed to increase the budget itself. This idea is similar in spirit to Skaperdas and Grofman (1995) who investigate voting contests where the political candidates have one unit of time or resource that they can allocate between positive campaigning (which attracts undecided voters) and negative campaigning (which reduces the number of undecided voters a competitor would have attracted in the absence of negative campaigning).¹

(iii) We do not model a rent-seeking contest where the contestants spend *money* to gain a prize or part of a price. In contrast, in our model the agents spend *time* to influence the sponsor. The total time endowment for lobbying is exogenously given and normalized to unity and it is divided by any individual bureaucrat into time spent for antagonistic lobbying and time spent for joint lobbying. This is in strong contrast to most of the usual lobbying models which deal with campaign contributions and the like, that is, with monetary expenditures whose total amount is not exogenously given – on the contrary, its endogenous determination is the basis of rent dissipation and the literature then asks the question of how far various institutional settings influence the extent of rent dissipation. The present paper has nothing to do with rent dissipation, it is directed at totally different questions, in particular, at the incentive effects that various income schedules exert on the lobbying efforts of public-sector employees and civil servants.

(iv) We distinguish various types of bureaucratic incomes:

- exogenously fixed incomes,
- incentive incomes which alternatively depend on the total departmental budget or

on the individual sub-budget which is administrated by the bureaucrat in question. It will be shown that incentive incomes do not necessarily lead to lobbying strategies which differ from those chosen in the case of fixed incomes.

The paper is organized as follows. Section 2 presents the model, defining how joint lobbying determines the total departmental budget und how antagonistic lobbying characterizes the contest among the bureaucrats. The model extends Skaperdas's (1992) approach by the explicit inclusion of bureaucratic income schedules and by explicit constraints on the individual budgets the bureaucrats have to administrate. In Section 3 we present the Nash equilibrium in lobbying efforts. We deal with existence and uniqueness and give an overview of the various possible types of lobbying equilibria. Section 4 is devoted to the characterization of several interesting types of equilibria, namely *full cooperation* (no antagonistic lobbying), *polarization* (one agent fully concentrates on antagonistic lobbying, the other fully concentrates on joint lobbying), and *split lobbying* (interior solutions for both lobbying efforts of both agents). Finally, in Section 5 we show that any bureaucrat spends as much money as possible for pure waste, regardless of whether he is paid a fixed income or any sort of incentive income. A brief conclusion follows. There are several appendices which will be sent to the reader on request.

2 The model

We consider a department which consists of two bureaucrats. The sponsor, for example the minister or the parliament, appropriates a departmental budget to finance a particular project which is jointly produced by both bureaucrats. However, the bureaucrats do not draw personal satisfaction from the total departmental budget, but only from the individual budgets they have to administrate, which are some shares of the total departmental budget. Therefore, the bureaucrats engage in double lobbying: they lobby jointly to get a high departmental budget, and they lobby antagonistically to get a high individual share in this total budget. We assume that the bureaucrats spend $x_i, i = 1, 2$ time units for joint lobbying and y_i time units for antagonistic lobbying, where $x_i + y_i = 1$. The assumption of an exogenously fixed time endowment for lobbying may seem to be restrictive. However, the qualitative results of the paper remain unchanged if the total time spent for lobbying is endogenized. This is shown in Appendix A.4.

The effects of the various types of lobbying are captured by the following Assumptions 1 and 2. Lobbying is private information, and cannot be verified

before a court.

Assumption 1 (joint lobbying): The total departmental budget $B(x_1, x_2)$ is a function of the joint-lobbying efforts x_1 and x_2 . The budget-formation function is twice continuously differentiable. It exhibits positive but non-increasing marginal products, $B_1 > 0$, $B_2 > 0$, $B_{11} \leq 0$ and $B_{22} \leq 0$.² The cross derivative B_{12} can be zero, positive, or negative. $B(0, 0) = 0$, $B(1, 1) = \bar{B}$.

The budget-formation function $B(x_1, x_2)$ can be interpreted in the same way as a standard production function that abstracts from the exact technological and organizational details of the production process. How effective an agent is in his joint lobbying is measured by his marginal product B_i . The budget is bounded both from above and from below. First, $B(1, 1) = \bar{B}$ is the maximum budget which can be achieved by joint lobbying, so there is no danger that an infinite budget might arise, even in the special case where the budget-formation function exhibits constant returns to scale.³ Second, $B(0, 0) = 0$ is the minimum budget: joint lobbying is a necessary condition for any budget, since the sponsor would not even know of the project unless he learned of it by the lobbying of the bureaucrats. The normalization to zero has been made for convenience. The analysis would become more complicated without further economic insight if we assumed that $B(0, 0) = B^{min}$, with B^{min} as a minimum budget which the sponsor in any case would appropriate for the realization of the project at stake. Note that the combination of the assumptions $B(0, 0) = 0$ and $B_i > 0$, $i = 1, 2$ implies that $B(0, x_2) > 0$ and $B(x_1, 0) > 0$. This excludes budget-formation functions where a budget is only appropriated if both bureaucrats engage in joint lobbying.⁴ Therefore, situations in which one bureaucrat fully specializes in antagonistic lobbying may be equilibria of the game with a non-zero departmental budget.

Let us next turn to the individual budgets of the two bureaucrats. The bureaucrats engage in a lobbying contest to try to get as high a share of the departmental budget as possible. The antagonistic-lobbying efforts y_i determine the splitting of the departmental budget: the more time an agent devotes to antagonistic lobbying, the higher his individual share.

Assumption 2 (antagonistic lobbying): p is the share of the budget that is finally administrated by bureaucrat 1, a share $(1 - p)$ is administrated by bureaucrat 2. These shares depend on the antagonistic-lobbying efforts y_1 and y_2 . The contest-success function $p(y_1, y_2)$ is twice continuously differentiable and has the following properties:

- $p(y_1, y_2) \in [0, 1] \quad \forall y_1, y_2 \in [0, 1]$ (share of the budget),
- $p_1 > 0, p_2 < 0, p_{11} < 0, p_{22} > 0$ ⁵ (antagonistic lobbying y_i has positive but decreasing marginal products),
- $p(y_1, y_2) = 1 - p(y_2, y_1)$ (anonymity of agents).

Note that the anonymity of agents implies that equal lobbying induces equal budgets, $p(y, y) = 1/2$. Assumption 2 defines a contest-success function. How effective an agent is in his antagonistic lobbying is measured by p_i , his marginal success in increasing his share of the departmental budget. As an example of a contest-success function the reader may refer to Tullock's (1980) ratio model $p = y_1/(y_1 + y_2)$, which exhibits decreasing marginal effectiveness of antagonistic-lobbying efforts. Assumption 2 of this paper can be fulfilled by the Tullock ratio model, except for $y_1 = y_2 = 0$.⁶ On the other hand, Assumption 2 is not fulfilled by Hirshleifer's (1989) logistic contest-success function $p = 1/(1 + \exp(k(y_2 - y_1)))$, which implies convexity of p if $y_1 < y_2$ and concavity thereafter.⁷

The bureaucrats are paid an income for their activities. Details on the various possible income schedules are presented in Assumption 3.

Assumption 3 (income schedules): Denote by I the income of bureaucrat 1 and by J the income of bureaucrat 2. There are three alternative income schedules:⁸

- fixed incomes: $I = \bar{I}, J = \bar{J}, \quad \bar{I} = \bar{J} = 0$ if $B = 0$;
- incentive incomes depending on the total budget:

$$I = I(B), \quad I' > 0, I'' < 0, I(0) = 0,$$

$$J = J(B), \quad J' > 0, J'' < 0, J(0) = 0,$$
- incentive incomes depending on the individual budgets:

$$I = I(pB), \quad I' > 0, I'' < 0, I(0) = 0,$$

$$J = J((1 - p)B), \quad J' > 0, J'' < 0, J(0) = 0.$$

Note that the sponsor can only observe the total departmental budget and the individual budgets and, therefore, the bureaucratic incomes can only be conditioned on these budgetary values. The sponsor could not condition incomes on lobbying efforts which are unobservable. The sponsor also does not know that $x_i + y_i = 1$, otherwise he could calculate the lobbying efforts on the basis of his observation of the total and of the individual budgets. For the results of this paper we do not need an explicit model for the determination of the bureaucratic incomes. This renders our results fairly general. In particular, the incentive incomes can be any type of non-linear concave functions.

We allow that circumstances from outside the model influence the bureaucratic incomes. By way of example, the duration of individual employment may be relevant for the payment, or special bonus schemes may be awarded to restrain a bureaucrat from accepting an outside job. Therefore, we have assumed that the agents may earn different fixed incomes \bar{I}, \bar{J} or different incentive incomes $I(\cdot), J(\cdot)$. Of course, our specifications include the special cases of equal incomes $\bar{I} = \bar{J}$, or $I(B) = J(B) \forall B$. Similarly, if incentive incomes are conditioned on the individual budgets, the income schedules may well be identical, $I(b) = J(b) = f(b) \forall b$, where b is the individual budget. In this case the agents get equal incomes if their individual budgets are the same, for instance, because both apply the same strategies, $y_1 = y_2$, whence $p = 1/2$.

The bureaucrats are egoistic individuals. They want to earn a high income, but they also get satisfaction from the administration of a high individual budget. Therefore, their individual utilities consist of a weighted average of their individual budgets and of their personal incomes, where the weights are given by $\theta_i \in (0, 1)$, $i = 1, 2$.

$$U_1 = \theta_1 pB + (1 - \theta_1)I, \quad (1)$$

$$U_2 = \theta_2 (1 - p)B + (1 - \theta_2)J. \quad (2)$$

There are several particularities of these specifications which should briefly be mentioned. First, the linearity of utility has merely been chosen for convenience. All propositions of the paper are also valid if the more general utility functions $U_1(pB, I)$ and $U_2((1-p)B, J)$ are considered.⁹ Second, we have intentionally excluded the case of $\theta_i = 0$. In this case there would be no incentive to antagonistic lobbying if the incomes depend on the total budget. Third, it would not be meaningful to deduct disutility from lobbying as further argument in the bureaucrats' utility functions. Since the total amount of lobbying is exogenously given ($x_i + y_i = 1$), and the bureaucrats only split total lobbying into two sub-lobbying activities, their disutility from lobbying is always the same. If such a constant disutility were introduced into the utility functions, it would not change any marginal condition.

The bureaucrats face the following budget constraints. First, there is the total departmental budget appropriated by the sponsor,

$$B \geq I + J + 2\bar{K}, \quad (3)$$

where I, J correspond to any of the three income schedules treated in the paper and $2\bar{K}$ are exogenously given capital investments which are necessary for the completion of the project. The budget constraint is written as an inequality to allow for

bureaucratic waste: if the total budget B is strictly greater than the agents' incomes and the capital investments, the excess money is used for pure waste, for instance for unnecessary buildings, marble staircases in these buildings, large cars, hiring of further unproductive employees and the like. If the project is not performed, we trivially assume that $\overline{K} = 0$ and that there is no waste. Only the bureaucrats know the technology which determines $2\overline{K}$, only they can tell apart money that is spent for capital investments and money that is spent for waste. The sponsor only observes what he pays, that is, B, I and J . Therefore, the budget constraint is "soft:" if the bureaucrats succeed in inducing the sponsor to appropriate a budget in excess of I, J plus $2\overline{K}$, they can use the excess money for pure waste.

The sponsor splits the total budget into two individual budgets which are as soft as the total budget. For convenience we assume that for his individual productive activities each bureaucrat needs capital investments of \overline{K} . Then, the two individual budget constraints can be written as follows:

$$pB \geq I + \overline{K}; \quad (1-p)B \geq J + \overline{K}. \quad (4)$$

If a bureaucrat did not comply with his budget constraint, he would be fired or, alternatively, be subject to an extremely unpleasant monitoring by the sponsor and the media. Hence, when dividing his effort between joint and antagonistic lobbying, any bureaucrat explicitly takes account of his individual budget constraint.

3 Equilibrium

3.1 Feasibility of the project

Our model is characterized by many exogenous constants, for instance the capital investments \overline{K} and, in the case of fixed incomes, $\overline{I}, \overline{J}$. Moreover, there are many functions whose shape is exogenously given, such as $B(\cdot)$, or the income schedules $I(\cdot), J(\cdot)$. Therefore, one could well think of situations where even extremely high joint lobbying would not attain a departmental budget that is high enough to finance the project: consider, for instance, a situation where $\overline{B} := B(1, 1) = 500$ mill. Euro, whereas the project requires capital investments of $2\overline{K} = 2$ billion Euro. In this case the bureaucrats will forget about this project and neither engage in joint lobbying nor in antagonistic lobbying.

Therefore, before playing the lobbying game, the agents check the feasibility of the project.¹⁰ For this purpose hypothetical lobbying efforts are calculated by the

agents, taking as given the efforts of the other agent. We always choose antagonistic lobbying y_i as instrument variables. Therefore, the bureaucrats consider utilities $U_i(y_1, y_2)$, contest success $p(y_1, y_2)$ and a departmental budget $B(1 - y_1, 1 - y_2)$.¹¹ Any agent's maximization has to take into account the boundaries of $y_i \in [0, 1]$. Therefore, the agents apply the following optimization approach:

$$\max_{y_1 \in [0, 1]} \theta_1 p B + (1 - \theta_1) I, \quad (5)$$

$$\max_{y_2 \in [0, 1]} \theta_2 (1 - p) B + (1 - \theta_2) J. \quad (6)$$

The bureaucrats' calculations lead to Nash values $\hat{x}_i, \hat{y}_i, i = 1, 2$.¹² The project is considered not to be feasible if

$$p(\hat{y}_1, \hat{y}_2) B(\hat{x}_1, \hat{x}_2) < I + \overline{K}, \quad (7)$$

and/or

$$(1 - p(\hat{y}_1, \hat{y}_2)) B(\hat{x}_1, \hat{x}_2) < J + \overline{K}, \quad (8)$$

where I and J refer to all kinds of income schedules as defined in Assumption 3. Note that the bureaucrats ignore the individual budget constraints in their hypothetical optimization (5) and (6). Therefore they attain hypothetical effort levels which may fulfill or not fulfill these individual constraints. If at least one constraint is not fulfilled, the project is considered not to be feasible. In this case, the bureaucrats exert neither joint nor antagonistic lobbying, the incomes and the capital investments are equal to zero.

The chosen feasibility criterion, conditions (7) and (8) is the most plausible one for the following reasons. Both players know that they await harsh punishment if they violate the individual budget constraints. First, violation may imply dismissal, and this is not only feared by the dismissed bureaucrat but also by his fellow because it takes time to find replacement and it takes time to set up the necessary relationship with a new colleague (which type of budget-formation function $B(\cdot)$ will hold with a newcomer, is unknown to the bureaucrat who is not fired). Second, if violation does not imply direct dismissal, but being exposed to strong criticism by the superiors and by the media, this also throws bad light on the other bureaucrat and, therefore, he prefers not to follow up a project where his fellow bureaucrat cannot fulfill his individual budget constraint.

3.2 Determination of the equilibrium

Let us now assume the project has passed the test of feasibility. This implies that both bureaucrats know that their individual budget constraints will not be violated

if the project is performed. Therefore, it is not necessary to explicitly consider these constraints in the bureaucrats' lobbying game: each agent decides how to split his lobbying in order to maximize his utility, taking as given the lobbying activities of the other agent. This is the same optimization as shown in (5) and (6) above. The Lagrangean functions of the agents' optimization approaches are as follows:

$$\theta_1 pB + (1 - \theta_1)I + \lambda_{11}(1 - y_1) + \lambda_{12}y_1, \quad (9)$$

$$\theta_2(1 - p)B + (1 - \theta_2)J + \lambda_{21}(1 - y_2) + \lambda_{22}y_2, \quad (10)$$

where λ_{ij} are the Lagrangean parameters. The first-order conditions are different according to the type of income schedule. For agent 1, we obtain

$$I = \bar{I} : \quad [p_1 B - pB_1] \theta_1 - \lambda_{11} + \lambda_{12} = 0, \quad (11)$$

$$I = I(B) : \quad [p_1 B - pB_1] \theta_1 - (1 - \theta_1)I'B_1 - \lambda_{11} + \lambda_{12} = 0, \quad (12)$$

$$I = I(pB) : \quad [p_1 B - pB_1] \{\theta_1 + (1 - \theta_1)I'\} - \lambda_{11} + \lambda_{12} = 0, \quad (13)$$

$$\forall I : \quad \lambda_{11}(1 - y_1) = 0, \quad \lambda_{12}y_1 = 0, \quad \lambda_{11}, \lambda_{12} \geq 0. \quad (14)$$

Analogous first-order conditions hold for agent 2.¹³

The bureaucrats' first-order conditions determine reaction functions $y_1(y_2)$, $y_2(y_1)$. A Nash equilibrium y_1^N , y_2^N of the game is a fixed point $y_1^N = y_1(y_2(y_1^N)) \wedge y_2^N = y_2(y_1(y_2^N))$.

Proposition 1: (i) There exists a Nash equilibrium y_1^N, y_2^N of the game. (ii) Under a fairly complicated special assumption (which differs according to the income schedule) this equilibrium is unique.

Proof: presented in Appendix A.1 which will be sent to the reader upon request.

3.3 Equilibrium strategies and income schemes

It can be shown that fixed incomes induce the same behavior as incentive incomes that depend on the agents' individual budgets. This is a challenging result since a priori one would have expected that the explicit stipulation of an incentive income should decisively change the behavior of the bureaucrats.

Proposition 2: The Nash-equilibrium strategies y_i^N are identical for fixed incomes and for incomes that depend on the individual budgets.

Proof: Compare the first-order conditions (11) and (13). The term $[p_1 B - pB_1]$ is equal in both conditions. In (11) this term is multiplied by $\theta_1 > 0$, in (13) by

$\theta_1 + (1 - \theta_1)I' > 0$. An analogous interpretation holds for the marginal conditions of the second bureaucrat.

Now consider interior solutions $y_i \in [0, 1]$, whence $\lambda_{ij} = 0$, $i = 1, 2$. Then the following system of two equations in the two unknown variables y_1, y_2 determines the strategies both in the case of fixed incomes and of incomes that depend on the individual budgets: (a) $p_1B - pB_1 = 0$, and (b) $-p_2B - (1 - p)B_2 = 0$. Since we have proved the uniqueness of the Nash equilibria, the strategies must therefore be identical in both cases. The extension to corner solutions is straightforward. \square

Proposition 2 has the following intuitive explanation. Consider bureaucrat 1 (the story for bureaucrat 2 is analogous). If this agent earns a fixed income, he has lobbying incentives that result from his interest in a high individual budget, that is, from the term $\theta_1 pB$ in his utility function. If his income depends on the individual budget, he has exactly the same lobbying incentives. First, he is directly interested in his individual budget, $\theta_1 pB$, and second, he is interested in his personal income which also is a function of his individual budget, $(1 - \theta_1)I(pB)$. Therefore, this income schedule does not change the lobbying strategies as compared with a fixed income. This is different if the incentive income depends on the total budget. Then agent 1 is directly interested in the individual budget, $\theta_1 pB$, whereas the income gives another lobbying incentive, namely in favor of joint lobbying, $(1 - \theta_1)I(B)$.

On the other hand, while Proposition 2 is plausible, it is definitely surprising. After all, a fixed income implies a utility function which is linear in the individual budget, whereas an incentive income, that depends on the individual budget, implies a utility function that is concave in the individual budget. Hence, the reader might have expected differences in the lobbying activities which would be similar to the differences in rent-seeking strategies of risk-neutral and risk-averse agents. We know from Konrad and Schlesinger (1997) that the risk-averse agent tends to spend less for rent-seeking because he fears the risk, but at the same time tends to spend more because this increases the likelihood of success; which effect dominates, depends on the specifications of the relevant functions and parameters. Note, however, that our model differs decisively from the type of rent-seeking model applied in Konrad and Schlesinger. First, in our model there is no risk. Neither θ_i nor p are probabilities. Second, the question of more or less expenditures for lobbying is a non-question in our model since the total investment in lobbying is always unity; it is only the split-up of the lobbying activities which matters. Third, the concavity of I and J is set by the sponsor and not by the bureaucrats.

3.4 Types of equilibria

Let us distinguish the following three types of equilibria:¹⁴

- ‘Full conflict’ refers to an equilibrium where $y_1^N = y_2^N = 1$, that is, there is no joint lobbying, but only antagonistic lobbying.
- ‘Full cooperation’ refers to an equilibrium where $y_1^N = y_2^N = 0$, that is, the bureaucrats spend all their time for joint lobbying, there is no antagonism.
- ‘Partial cooperation’ comprises all other equilibria, for instance:¹⁵
 - both bureaucrats split their efforts between joint and antagonistic lobbying,
 - one bureaucrat devotes all his effort to joint lobbying, whereas the other splits his effort,
 - one bureaucrat devotes all his effort to antagonistic lobbying, whereas the other splits his effort,
 - one bureaucrat devotes all his effort to joint lobbying, the other devotes all his effort to antagonistic lobbying.

After presenting this typology, we immediately recognize that a full-conflict equilibrium is precluded in our model.

Proposition 3: Full conflict ($y_1^N = y_2^N = 1$) can never be an equilibrium.

Proof: $y_1^N = y_2^N = 1$ implies $x_1^N = x_2^N = 0$, $B(0,0) = 0$. This implies utilities $U_1(0,0) = U_2(0,0) = 0$. Any joint lobbying activity will increase the utility of at least one agent. \square

4 Characterization of the equilibria

4.1 Rewriting the first-order conditions

For the following characterization of the various types of equilibria we will rewrite the first-order conditions (11) to (13). For this purpose let us assume that the budget-formation function B exhibits constant returns to scale. This implies $B(x_1, x_2) = x_1 B_1(x_1, x_2) + x_2 B_2(x_1, x_2)$. Therefore, the first-order conditions of the bureaucrats’ optimization approach can be written as

$$p_1 x_1 B_1 + p_1 x_2 B_2 - \mathcal{L}_1 B_1 \gtrless 0, \quad (15)$$

$$-p_2x_1B_1 - p_2x_2B_2 - \mathcal{L}_2B_2 \gtrless 0, \quad (16)$$

where all functions are evaluated at the relevant equilibrium strategies (y_1^N, y_2^N) . The rewritten first-order conditions reveal the most important consequences of the assumption of constant returns to scale: it does not matter how effective the bureaucrats are in their joint lobbying. What really matters is the ratio B_1/B_2 : is agent 1 more effective in joint lobbying than agent 2?

The differences in income schedules are captured by the variables \mathcal{L}_i . They are identical for fixed incomes and for incomes that depend on the individual budgets,

$$\mathcal{L}_1 = p; \quad \mathcal{L}_2 = 1 - p. \quad (17)$$

In contrast, if the incomes depend on the total budget, we obtain

$$\mathcal{L}_1 = p + \frac{1 - \theta_1}{\theta_1} I'(B); \quad \mathcal{L}_2 = 1 - p + \frac{1 - \theta_2}{\theta_2} J'(B). \quad (18)$$

To get more insight into the rewritten first-order conditions, consider the following two extreme scenarios. First, for the sake of the argument, assume that antagonistic lobbying is fully ineffective, $|p_i| = 0$. We ignore for the moment that this contradicts Assumption 2. It can easily be seen that in this case there is no incentive to antagonistic lobbying whatsoever. We substitute into (15) and (16) and obtain¹⁶

$$-\mathcal{L}_1B_1 < 0 \Rightarrow y_1 = 0; \quad -\mathcal{L}_2B_2 < 0 \Rightarrow y_2 = 0. \quad (19)$$

Second, consider the scenarios where $p_1 = \mathcal{L}_1/x_1^N$ or $-p_2 = \mathcal{L}_2/x_2^N$. Then antagonistic lobbying is highly effective: a bureaucrat who faces so large a $|p_i|$ will devote all of his time to fight his colleague.¹⁷ We substitute into (15) and (16) and get

$$p_1x_2B_2 > 0 \Rightarrow y_1^N = 1; \quad -p_2x_1B_1 > 0 \Rightarrow y_2^N = 1. \quad (20)$$

The two extreme scenarios illustrate that it will be the straightforward way to characterize the various types of equilibria by the particular boundaries of the effectiveness of antagonistic lobbying.

4.2 Full cooperation

Full cooperation is given if the bureaucrats do not exert any antagonistic lobbying, $y_1^N = y_2^N = 0$. In this case the agents face the following conditions

$$p_1x_1B_1 + p_1x_2B_2 - \mathcal{L}_1B_1 \leq 0, \quad (21)$$

$$-p_2x_1B_1 - p_2x_2B_2 - \mathcal{L}_2B_2 \leq 0. \quad (22)$$

We substitute the particular properties of the full-cooperation case, that is, $x_1^N = x_2^N = 1$, and $p_1(0, 0) = -p_2(0, 0)$.¹⁸ Then we combine the conditions for agent 1 and agent 2 and obtain

$$\frac{\mathcal{L}_2 - p_1}{p_1} \geq \frac{B_1}{B_2} \geq \frac{p_1}{\mathcal{L}_1 - p_1}. \quad (23)$$

It can easily be shown that these two inequalities can only hold if

$$p_1 \leq \frac{\mathcal{L}_1 \mathcal{L}_2}{\mathcal{L}_1 + \mathcal{L}_2}. \quad (24)$$

Since in the full-cooperation case $p_1 = -p_2$, the same upper limit holds for the second bureaucrat. This upper limit is particularly simple for fixed incomes and for incomes that depend on the individual budgets. Recall that Assumption 2 requires $p(0, 0) = 1/2$. Therefore, we have $\mathcal{L}_1 = \mathcal{L}_2 = 1/2$ which implies

$$p_1 \leq 1/4; \quad -p_2 \leq 1/4. \quad (25)$$

Proposition 4: (i) Full cooperation can occur as an equilibrium of the game if antagonistic lobbying is sufficiently ineffective.

(ii) If antagonistic lobbying is extremely ineffective ($p_1 \rightarrow 0$), then full cooperation will occur regardless of how effective the agents are in their joint lobbying.

(iii) If antagonistic lobbying is low but relatively effective ($p_1 \rightarrow \mathcal{L}_1 \mathcal{L}_2 / (\mathcal{L}_1 + \mathcal{L}_2)$), full coordination requires equal efficiency in joint lobbying ($B_1 = B_2$) if the agents earn fixed incomes or incomes that depend on the individual budgets.

Proof: (i) follows directly from (24) and also from (25).

(ii) Substitute $p_1 \rightarrow 0$ into the conditions (23). Then, (23) converges to $\infty \geq B_1/B_2 \geq 0$.

(iii) Substitute $p_1 = \mathcal{L}_1 \mathcal{L}_2 / (\mathcal{L}_1 + \mathcal{L}_2)$ into the conditions (23). The result is $\mathcal{L}_2/\mathcal{L}_1 \geq B_1/B_2 \geq \mathcal{L}_2/\mathcal{L}_1$ which can only hold if $B_1/B_2 = \mathcal{L}_2/\mathcal{L}_1$. For fixed incomes and incomes that depend on the individual budgets, we have $\mathcal{L}_1 = \mathcal{L}_2 = 1/2$ and, therefore $B_1 = B_2$. \square

Proposition 4(i) is fairly straightforward: it is kind of trivial that full cooperation occurs if antagonistic lobbying is sufficiently ineffective. More interesting are the statements of Proposition 4(ii) and 4(iii) which refer to the interplay between antagonistic and joint lobbying. If the agents are fully ineffective in antagonistic lobbying, it only matters that there is some effectiveness in joint lobbying.¹⁹ However, if the agents become more effective in antagonistic lobbying, full cooperation will only occur if they are similarly effective in joint lobbying, at least if they earn

fixed incomes or incomes that depend on the individual budgets. This result is due to the constant-returns-to-scale assumption which yields a maximum budget if both agents are equally effective. If the incentive incomes depend on the total budget, this result is changed because the different income schedules ($I'(B) \neq J'(B)$) give diverging incentives. Therefore, in this case relatively effective antagonistic lobbyists will in the full-cooperation equilibrium adjust to an inverse-effectiveness condition $B_1/B_2 = \mathcal{L}_2/\mathcal{L}_1$.

4.3 Partial cooperation

It would be tedious to present a detailed analysis of all the various types of partial cooperation. We rather restrict the discussion to the cases of *polarization* and *split lobbying*. We first consider *polarization* where bureaucrat 1 engages only in joint lobbying, $y_1^N = 0$, whereas bureaucrat 2 engages only in antagonistic lobbying, $y_2^N = 1$. The agents face the following conditions

$$p_1 x_1 B_1 + p_1 x_2 B_2 - \mathcal{L}_1 B_1 \leq 0, \quad (26)$$

$$-p_2 x_1 B_1 - p_2 x_2 B_2 - \mathcal{L}_2 B_2 \geq 0. \quad (27)$$

Substituting the particular properties of the polarization case, that is, $x_1^N = 1$ and $x_2^N = 0$, we obtain

$$p_1 \leq \mathcal{L}_1, \quad (28)$$

$$-p_2 \geq \mathcal{L}_2 \frac{B_2}{B_1}. \quad (29)$$

These conditions should be compared with the case of full cooperation, where the agents are relatively ineffective in their antagonistic lobbying. In contrast, in the polarization case the aggressive bureaucrat 2 is quite successful in the fight against the other player and less effective in the joint fight for the departmental budget. Bureaucrat 1, on the other hand, recognizes that antagonistic lobbying promises low success, although p_1 may well be higher than in the case of full cooperation. Consequently, bureaucrat 2 fully specializes in the hostile strategy, while bureaucrat 1 fully specializes in joint lobbying. We obtain the following proposition.

Proposition 5: Polarization with $y_1^N = 0$ and $y_2^N = 1$ can occur as an equilibrium of the game if the hostile agent is effective in antagonistic lobbying but less effective in joint lobbying. It is the other way round for the friendly agent.

Proof: follows directly from (28) and (29). □

Next we analyse the case of *split lobbying*, where both agents engage in both types of lobbying, $y_1^N, y_2^N \in (0, 1)$. The agents face the following first-order conditions

$$p_1 x_1 B_1 + p_1 x_2 B_2 - \mathcal{L}_1 B_1 = 0, \quad (30)$$

$$-p_2 x_1 B_1 - p_2 x_2 B_2 - \mathcal{L}_2 B_2 = 0, \quad (31)$$

which can be rewritten as

$$p_1 = \frac{\mathcal{L}_1}{x_1 + x_2 B_2 / B_1} < \frac{\mathcal{L}_1}{x_1}, \quad (32)$$

$$-p_2 = \frac{\mathcal{L}_2}{x_2 + x_1 B_1 / B_2} < \frac{\mathcal{L}_2}{x_2}. \quad (33)$$

To evaluate this result recall the extreme scenarios mentioned in subsection 4.1, where $p_1 = \mathcal{L}_1/x_1^N$ or $-p_2 = \mathcal{L}_2/x_2^N$ were shown to induce full antagonistic lobbying. The conditions (32) and (33) show that in a split-lobbying equilibrium the values of p_1 and $-p_2$ are significantly below these upper limits. On the other hand, p_1 and $-p_2$ must be larger than in the case of full cooperation. Therefore, we have the following proposition:

Proposition 6: A split-lobbying equilibrium requires medium efficiency in antagonistic lobbying, where “medium efficiency” means

$$\frac{\mathcal{L}_1}{x_1} \bigg|_{y_1^N=y_2^N=1} > p_1 > \frac{\mathcal{L}_1 \mathcal{L}_2}{\mathcal{L}_1 + \mathcal{L}_2} \bigg|_{y_1^N=y_2^N=0}.$$

Proof: follows directly from (32) and (33), and a comparison with (24). \square

Any more detailed interpretation of the equalities in (32) and (33) is tricky, since both sides of the equalities are determined by the strategies y_1^N and y_2^N . However, a particular connection between antagonistic and joint lobbying can be found by dividing the equalities in (32) and in (33). This yields

$$\frac{p_1}{-p_2} = \frac{\mathcal{L}_1}{\mathcal{L}_2} \cdot \frac{B_1}{B_2}. \quad (34)$$

Accordingly, split lobbying requires a proportionality between the relative efficiency of antagonistic and joint lobbying, the proportionality factor being $\mathcal{L}_1/\mathcal{L}_2$. This factor is equal to unity if the agents' incomes are fixed or depend on the individual budgets, *and* if these agents spend the same amount of effort for antagonistic lobbying ($y_1^N = y_2^N \Rightarrow p = 1/2 \Rightarrow \mathcal{L}_1 = \mathcal{L}_2$).

To provide a better intuitive feeling of what goes on in a split-lobbying case, let us calculate a simple example for fixed incomes and incentive incomes that depend on the individual budgets ($\mathcal{L}_1 = p, \mathcal{L}_2 = 1 - p$). We choose a constant-returns-to-scale technology $B = ax_1 + x_2$, where the first agent is more effective in joint lobbying, $a > 1$. The contest-success function is specified according to Tullock (1980), $p = y_1/(y_1 + y_2)$. Then we have $p_1 = y_2/(y_1 + y_2)^2$ and $-p_2 = y_1/(y_1 + y_2)^2$. Split lobbying requires

$$p_1 = \mathcal{L}_1 B_1 / B, \quad (35)$$

$$-p_2 = \mathcal{L}_2 B_2 / B. \quad (36)$$

Substituting for p_i, \mathcal{L}_i, B_i and B , we obtain the following system of equations:

$$ay_1^2 + y_2^2 + 2ay_1y_2 - (1 + a)y_2 = 0, \quad (37)$$

$$ay_1^2 + y_2^2 + 2y_1y_2 - (1 + a)y_1 = 0. \quad (38)$$

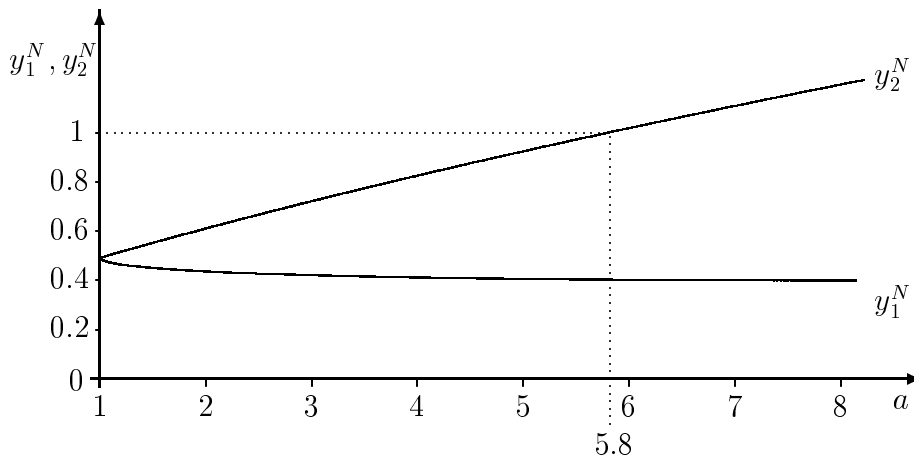

Figure 1: Antagonistic strategies (example)

Figure 1 presents the antagonistic-lobbying strategies which result from the example.²⁰ If $a = 1$, both agents split their activity evenly between antagonistic and joint lobbying ($y_1^N = y_2^N = 0.5$). For $a > 1$, both agents concentrate on that type of lobbying in which they have a relative advantage: agent 1 devotes more than 50 per cent of his time for joint lobbying, agent 2 spends more than 50 per cent of his time for antagonistic lobbying. Increasing a implies a sharp increase in agent 2's hostility, while it only leads to a weak increase of agent 1's joint lobbying. Too pronounced differences in the effectiveness of joint lobbying make split lobbying impossible: if a exceeds $3 + 2\sqrt{2} \simeq 5,828$, agent 2 will fully engage in antagonistic lobbying, choosing $y_2^N = 1$ and, therefore, leave the split-cooperation case.

5 Remarks on the extent of pure waste

Until now we have investigated the choice of the bureaucrats' lobbying investments: after checking the feasibility of the project, the agents maximize their objective functions with respect to the antagonistic lobbying efforts y_1 and y_2 . The feasibility check guarantees that the individual budget constraints are never violated. They may be binding or non-binding at the agents' Nash equilibrium. This implies four possible cases as shown in figure 1.²¹

$pB = I + \overline{K}$ $(1 - p) = J + \overline{K}$	$pB > I + \overline{K}$ $(1 - p)B = J + \overline{K}$
$pB = I + \overline{K}$ $(1 - p)B > J + \overline{K}$	$pB > I + \overline{K}$ $(1 - p)B > J + \overline{K}$

Table 1: Individual budget constraints at the Nash equilibrium

These four cases differ with respect to the extent of pure waste. Whether any individual budget constraint is binding or not, depends on the agents' choice of lobbying and on the *exogenous framework*: the exogenously given functions p, B and I , and the exogenously given constant \overline{K} . Therefore, any of the four cases of Table 1 can occur, depending on the particular constellation of the framework of the model.

Let us rewrite the individual budget constraints by explicitly introducing pure waste as slack variables W_1, W_2 :

$$pB = I + \overline{K} + W_1, \quad (39)$$

$$(1 - p)B = J + \overline{K} + W_2. \quad (40)$$

The pure-waste variables measure the degree of slack in the individual budget constraints. For the following we concentrate on agent 1. The extension to agent 2 is straightforward.

The slack variable W_1 is zero if the particular constellation of the exogenous framework implies that at the agents' Nash equilibrium we have $pB = I + \overline{K}$. This constellation makes it impossible for the agent to devote money to waste. However, the framework may also allow for $pB > I + \overline{K}$, in which case pure waste occurs. The agent is always interested in fully exhausting the possibility of waste, since his utility is monotonically increasing in waste, as can easily be seen by substituting (39) into the agent's objective function:

$$\theta_1 pB + (1 - \theta_1)I \equiv \theta_1(I + \overline{K} + W_1) + (1 - \theta_1)I. \quad (41)$$

The Niskanen type of bureaucrat has no incentive whatsoever to return money to the sponsor; whenever it is possible he will use the money for waste. And this behavior is always the same regardless of the chosen income schedule: the incentive incomes do not reduce waste. We can formulate the following Proposition 7.

Proposition 7: If at the agents' Nash equilibrium the exogenous framework offers the possibility of pure waste, $pB > I + \overline{K}$, then this possibility will always fully be exhausted by the bureaucrat. This holds for a fixed income as well as for an incentive income regardless of whether it depends on the individual budget or on the total departmental budget.

Proof: trivial. □

6 Conclusion

This paper deals with the trade-off between joint lobbying and antagonistic lobbying. Joint lobbying determines the total budget that is awarded to a group of bureaucrats, whereas antagonistic lobbying characterizes the contest among the bureaucrats who fight each other to get a high share in the total budget. Each bureaucrat has to consider a budget constraint, that is, his budget must be sufficiently high to cover his personal income and his share of the investment costs. If a budget constraint is not binding, the remaining money is used for pure waste. We have obtained the following results:

- Fixed incomes induce the same behavior as incentive incomes that depend on the agents' individual budgets. Incentive incomes that depend on the total departmental budget give an incentive to increased joint lobbying.
- Full cooperation can occur as an equilibrium if antagonistic lobbying is sufficiently ineffective. "Split lobbying" requires medium efficiency in antagonistic lobbying. "Polarization," where one bureaucrat abstains from antagonistic lobbying whereas the other bureaucrat abstains from joint lobbying, is a Nash equilibrium if the hostile agent is effective in antagonistic lobbying but less effective in joint lobbying. It is the other way round for the friendly agent.
- The bureaucrats will always fully exhaust any possibility to spend money for pure waste. This holds for all the various types of incomes treated in this paper: incentive incomes do not reduce waste.

Recently, in most European countries there have been debates about the introduction of incentive payments for civil servants and employees in the public

sector. Starting from models of private firms the efficiency-improving consequences of incentive incomes have been taken for granted and, accordingly, the incentive schedules often have been seen as a panacea against public-sector inefficiencies. Counterarguments in the public discussion typically refer to the multidimensionality of the tasks performed by civil servants or employees in the public sector. A good example is the recent German debate about the introduction of incentive salaries for university professors. The present paper challenges the belief in the superiority of incentive payments in the public sector even for the case of one-dimensional tasks. It is shown that bureaucrats whose income depends on their individual budgets behave exactly in the same way as bureaucrats who are paid a fixed income.

Notes

¹There are various other papers whose models differ decisively from ours, but that also distinguish between efforts that increase the prize for the group and efforts which increase the individual share in this prize. See, for instance, Glazer's (2002) distinction between external and internal rent seeking and Inderst et al.'s (2002) distinction between inter-divisional and intradivisional contests in hierarchical firms. In Konrad (2000) the agents choose rent-seeking efforts which increase the probability to gain a prize and sabotage efforts which reduce the probability that other contestants get the prize.

²The subscripts denote partial derivatives.

³This assumption will be made in section 4 below, but only in this very section.

⁴Functions of this type produce particular problems with respect to the uniqueness of equilibria. See, for instance, Skaperdas (1992: 724).

⁵We do not impose any restrictions on the cross derivative p_{12} .

⁶An interesting contest-success function is presented in Nitzan (1991a: 1524) and in Nitzan (1991b: 44). In these papers a proportion a of the rent is distributed on egalitarian grounds and the rest is distributed according to relative effort. In our paper this would imply a specification $p = a \cdot 1/2 + (1 - a) \cdot y_1/(y_1 + y_2)$. In the same way as Tullock's ratio model, Nitzan's function is not well-defined if $y_1 = y_2 = 0$.

⁷Hirshleifer's function is, for example, applied in Skaperdas (1992). In our model it is not guaranteed, and in fact it is impossible for a large class of problems, to guarantee the existence of interior equilibria in the case of the Hirshleifer function, whereas the Tullock function leads to robust interior solutions. Compare Körber and Kolmar (1996).

⁸A straightforward extension of our model would refer to income schedules which combine the three alternatives mentioned in Assumption 3, for instance, $I = \beta_1 \bar{I}_1 + \beta_2 I_2(B) + \beta_3 I_3(pB)$.

⁹With positive first derivatives and weakly negative second derivatives.

¹⁰Such a first stage on the decision of whether to enter the game or not can implicitly be found in Katz et al. (1990), Nitzan (1991), Davis and Reilly (1999) – they all restrict the analysis to interior solutions of lobbying, thus excluding the case where the agents decide not to lobby at all. An explicit modelling of such a two-stage setting can be found in Wärneryd (1998) and Müller and Wärneryd (2001).

¹¹If no misunderstanding is possible, we will drop all functional dependencies of the various functions, that is to say, $p = p(y_1, y_2)$, $B = B(1 - y_1, 1 - y_2)$, etc.

¹²For existence and uniqueness of this Nash equilibrium see Appendix A.1 which will be sent to the reader on request.

¹³Replace p_1 with $-p_2$, p with $(1 - p)$, I' with J' and all subscripts '1' with subscripts '2.'

¹⁴Note that the terminology of this paper differs from Skaperdas (1992). The definition of full cooperation is the same, but partial cooperation in his paper only refers to Pareto-efficient outcomes of the game. We do not impose this restriction, hence, our definition is much wider. On the other hand, our definition of *full conflict* is much narrower than his definition of *conflict*.

¹⁵Details are given in appendix A.2.

¹⁶Note that $p_1 = 0$ implies $y_1^N = 0$, but that $y_1^N = 0$ may also occur for $p_1 > 0$. An analogous warning holds for the equations (20).

¹⁷The case where both agents face so large a $|p_i|$ was excluded in Proposition 3.

¹⁸This property follows from the anonymity of agents, see Assumption 2. Differentiate the equation $p(y_1, y_2) = 1 - p(y_2, y_1)$ with respect to y_1 to get $p_1(y_1, y_2) = -p_2(y_2, y_1)$ and evaluate at the equilibrium $y_1^N, y_2^N = (0, 0)$.

¹⁹This is wrong in Skaperdas (1992) who accentuates this requirement of (nearly) identical opportunity costs for *all* cases of full-cooperation equilibria.

²⁰Details of the solution of this system of equations are presented in Appendix A.3.

²¹If both constraints are binding, the constraints could directly be used to determine y_1 and y_2 , as shown in an example in the Appendix.

Appendix (not for publication)

A.1 Proof of Proposition 1²²

(i) Existence of the Nash equilibrium of stage 2 of the game:²³

The second-order conditions of U_1, U_2 with respect to y_1, y_2 are always fulfilled. For agent 1 the partial derivatives $\partial^2 U_1 / \partial y_1^2$ are as follows:

$$\begin{aligned} I = \bar{I} : & \quad [p_{11}B - 2p_1B_1 + pB_{11}] \theta_1 < 0, \\ I = I(B) : & \quad [p_{11}B - 2p_1B_1 + pB_{11}] \theta_1 + (1 - \theta_1)[I''B_1^2 + I'B_{11}] < 0, \\ I = I(pB) : & \quad [p_{11}B - 2p_1B_1 + pB_{11}] \{\theta_1 + (1 - \theta)I'\} + (p_1B - pB_1)^2(1 - \theta_1)I'' < 0. \end{aligned}$$

Analogous second-order conditions prevail for agent 2. The strict inequalities follow from Assumptions 1,2 and 3.

Both individuals' optimization problems are strictly convex, which implies that a maximizer exists and is unique. This guarantees the existence of reaction functions $y_1(y_2) : [0, 1] \times [0, 1] \rightarrow [0, 1]$, $y_2(y_1) : [0, 1] \times [0, 1] \rightarrow [0, 1]$. Furthermore, $p, p_1, p_2, B, B_1, B_2, B_{11}, B_{22}$ are all continuous, which implies that the reaction functions are continuous as well. The existence of an equilibrium is therefore a direct consequence of Brouwer's fixed-point theorem. \square

(ii) Uniqueness of the bureaucrats' Nash equilibrium.²⁴

In any equilibrium of stage 2 of the game we can either have $y_i^N \in (0, 1)$ or $y_i^N = \{0, 1\}$. In the latter case, it can either be characterized by $\partial U_i / \partial y_i = 0$ or $\partial U_i / \partial y_i \neq 0$. Equilibria in which the inequality condition is fulfilled for at least one individual will be called *boundary equilibria*, whereas all other equilibria will be called *interior equilibria*.

Lemma A.1: If there exists no equilibrium that is locally unstable, then the equilibrium y_1^N, y_2^N is unique.

Proof: See Skaperdas (1992), proof of Theorem 2. \square

Hence, it suffices to rule out local instability of equilibria.

Lemma A.2: Every boundary equilibrium y_1^N, y_2^N is locally stable.

Proof: A boundary equilibrium is characterized by $\partial U_i / \partial y_i < 0$ if $y_i = 0$ or by $\partial U_i / \partial y_i > 0$ if $y_i = 1$. In both cases there is no incentive to deviate from the corner solution. \square

Lemma A.3: An interior equilibrium y_1^N, y_2^N is locally stable if and only if $dy_1(y_2)/dy_2 \cdot dy_2(y_1)/dy_1 < 1$ at the equilibrium. This holds under a fairly complicated special assumption (which differs according to the income schedule).

The derivative of the reaction function of agent i with respect to a change in y_j can be derived by totally differentiating the first-order condition of agent i with respect to y_i and y_j (remember that we are in an interior equilibrium, hence $\partial U_i/\partial y_i = 0$). This yields

$$\frac{\partial y_i(y_j)}{\partial y_j} = -\frac{\frac{\partial^2 U_i}{\partial y_i \partial y_j}}{\frac{\partial^2 U_i}{\partial y_i^2}}, \quad i, j = 1, 2, i \neq j. \quad (\text{A.1})$$

Hence, local stability requires that

$$\frac{\frac{\partial^2 U_1}{\partial y_1 \partial y_2}}{\frac{\partial^2 U_1}{\partial y_1^2}} \frac{\frac{\partial^2 U_2}{\partial y_2 \partial y_1}}{\frac{\partial^2 U_2}{\partial y_2^2}} < 1. \quad (\text{A.2})$$

Consider the case of fixed incomes, $I = \bar{I}, J = \bar{J}$. Then the second derivatives in (A.2) are $\partial^2 U_1/\partial y_1^2 = \theta_1(p_{11}B - 2p_1B_1 + pB_{11})$, $\partial^2 U_1/(\partial y_1 \partial y_2) = \theta_1(p_{12}B - p_1B_2 - p_2B_1 + pB_{12})$, $\partial^2 U_2/\partial y_2^2 = \theta_2(-p_{22}B + 2p_2B_2 + (1-p)B_{22})$, and $\partial^2 U_2/(\partial y_2 \partial y_1) = \theta_2(-p_{12}F + p_1F_2 + p_2F_1 + (1-p)F_{12})$. Substituting in (A.2) yields the condition for local stability. For incentive incomes the various terms become more complicated, but the procedure is identical. \square

Lemmas 1 to 3 imply Proposition 1(ii). \square

(iii) Uniqueness in a special case.

If a departmental budget B is achieved by joint lobbying and this budget is binding, there may be a continuum of $\{x_1, x_2\}$ -values which lead to the same budget. Consider, for instance, the following case:

$$B(x_1, x_2) = x_1 + x_2,$$

where

$$B = \bar{I} + \bar{J} + 2\bar{K} = 1.$$

However, this continuum of solutions – a problem which is well-known from many public-good analyses – does not imply that there is a continuum of solutions in

stage 2 of our game. The binding departmental budget constraints requires binding individual constraints,

$$\begin{aligned} pB &= \bar{I} + \bar{K}, \\ (1-p)B &= \bar{J} + \bar{K}. \end{aligned}$$

Given Assumption 2,²⁵ this system of equation implies a unique solution $\{x_1^N, x_2^N, y_1^N, y_2^N\}$ in spite of the continuum of solutions for equation (A.3). Consider, for instance the following case where $p(y_1, y_2)$ is defined according to Tullock (1980), that is,

$$p(y_1, y_2) = \frac{y_1}{y_1 + y_2}.$$

Let us require, say,

$$pB = 0.4; \quad (1-p)B = 0.6.$$

Solving this system of equations for y_1 and y_2 yields the unique values of $y_1 = 0.4$ and $y_2 = 0.6$.

A.2 Types of equilibria

Table A.1 presents the precise characterization of the various Nash equilibria which may result from the one-shot game.²⁶ All functions are evaluated at the values given in columns y_1^N, y_2^N .

	eq. strategies		FOC		condition for existence
	y_1^N	y_2^N	ind. 1	ind. 2	
full cooperation:					
	0	0	$U_1^1 \leq 0$	$U_2^2 \leq 0$	$\frac{\mathcal{L} - p_1}{p_1} \geq \frac{B_1}{B_2} \geq \frac{p_1}{\mathcal{L} - p_1}.$
partial cooperation:					
split lobbying:	(0, 1)	(0, 1)	$U_1^1 = 0$	$U_2^2 = 0$	$\frac{x_2 p_1}{\mathcal{L}_1 - p_1 x_1} = \frac{B_1}{B_2} = \frac{\mathcal{L}_2 + p_2 x_2}{-p_2 x_1}$ $\wedge \quad \mathcal{L}_1 > p_1 x_1, \mathcal{L}_2 > -p_2 x_2$
coop. subm.1:	0	(0, 1)	$U_1^1 \leq 0$	$U_2^2 = 0$	$\frac{x_2 p_1}{\mathcal{L}_1 - p_1} \leq \frac{B_1}{B_2} = \frac{\mathcal{L}_2 + x_2 p_2}{-p_2}$ $\wedge \quad \mathcal{L}_1 > p_1, \mathcal{L}_2 > -p_2 x_2$
coop. subm.2:	(0, 1)	0	$U_1^1 = 0$	$U_2^2 \leq 0$	$\frac{p_1}{\mathcal{L}_1 - x_1 p_1} = \frac{B_1}{B_2} \leq \frac{\mathcal{L}_2 + p_2}{-x_1 p_2}$ $\wedge \quad \mathcal{L}_1 > p_1 x_1, \mathcal{L}_2 > -p_2$
conflict subm.1:	(0, 1)	1	$U_1^1 = 0$	$U_2^2 \geq 0$	$\frac{B_1}{B_2} \geq \frac{\mathcal{L}_2}{-x_1 p_2}$ $\wedge \quad \mathcal{L}_1 = p_1 x_1$
conflict subm.2:	1	(0, 1)	$U_1^1 \geq 0$	$U_2^2 = 0$	$\frac{B_1}{B_2} \leq \frac{x_2 p_1}{\mathcal{L}_1}$ $\wedge \quad \mathcal{L}_2 = -p_2 x_2$
polarization 1:	0	1	$U_1^1 \leq 0$	$U_2^2 \geq 0$	$\frac{B_1}{B_2} \geq \frac{\mathcal{L}_2}{-p_2}$ $\wedge \quad \mathcal{L}_1 \geq p_1$
polarization 2:	1	0	$U_1^1 \geq 0$	$U_2^2 \leq 0$	$\frac{B_1}{B_2} \leq \frac{p_1}{\mathcal{L}_1}$ $\wedge \quad \mathcal{L}_2 \geq -p_2$

Table A.1: Equilibrium strategies and conditions for their existence.

(FOC as defined in (11) to (13); coop. = cooperation, subm. = submission.

$$U_i^i := \partial U_i / \partial y_i, \quad i = 1, 2.)$$

A.3 Split lobbying: the calculation of the example

This example was calculated using Maple V Release 5.²⁷ The relevant equations

$$ay_1^2 + y_2^2 + 2ay_1y_2 - (1+a)y_2 = 0, \quad (37)$$

$$ay_1^2 + y_2^2 + 2y_1y_2 - (1+a)y_1 = 0. \quad (38)$$

imply the following feasible solutions:

$$y_1^N(a) = \frac{1}{2} \cdot \frac{(4\sqrt{a}-4)(1+a)}{(4a-4) \left(\frac{(4\sqrt{a}-4)a}{4a-4} - \frac{(4\sqrt{a}-4)}{4a-4} + 1 \right)},$$

$$y_2^N(a) = \frac{1}{2} \cdot \frac{(4\sqrt{a}-4)(1+a)}{4a-4}.$$

These solutions for y_1^N and y_2^N are presented in figure 1 in the text. The following solutions are infeasible:

- $y_1 = y_2 = 0$: Since we use the Tullock contest-success function $p = y_1/(y_1 + y_2)$, neither p , nor p_1 , nor p_2 are defined in our example if $y_1 = y_2 = 0$.
- $y_1 = \frac{1+a}{a-1}$; $y_2 = -\frac{1+a}{a-1}$: Every positive y_1 is matched by a negative y_2 and vice versa. This violates the non-negativity constraints for y_1 and y_2 (Assumption 2).

A.4 Endogenizing the sum of lobbying efforts

In the text we have assumed that the total time endowment for lobbying is exogenously given, $x_i + y_i = 1$. In this extension we show that this assumption can easily be given up without changing the qualitative results.

Let us assume that the agents split their total endowment of time into joint-lobbying efforts x_i , antagonistic-lobbying efforts y_i and productive efforts e_i , where $x_i + y_i + e_i = 1$, $i = 1, 2$. We assume that $e_i \in [e_i^{\min}, 1]$, where $e_i^{\min} > 0$ are the minimal amounts of productive efforts the bureaucrats must exert unless they will be fired. This implies the assumption that the bureaucrats must produce at least a minimal amount of output. Although the sponsor cannot exactly observe the agents' output, he recognizes if the public-good supply falls below some very low threshold. Maybe, it is the media which make him recognize this far-reaching failure of the bureaucrats.

The explicit introduction of productive efforts refers to the following production technology.

Assumption 1* (production technology, joint lobbying): The total departmental budget consists of the monetary expenditures for a particular public good plus additional money which results from joint lobbying:

$$B = G(e_1, e_2, 2\overline{K}) + L(x_1, x_2).$$

The functions G and L are twice continuously differentiable. They exhibit positive but non-increasing marginal products, $B_1 > 0$, $B_2 > 0$, $B_{11} \leq 0$ and $B_{22} \leq 0$; $L_1 > 0$, $L_2 > 0$, $L_{11} \leq 0$ and $L_{22} \leq 0$. The cross derivatives B_{12} and L_{12} may be zero, positive, or negative. $L(0, 0) = 0$, $L(1 - e_1^{min}, 1 - e_2^{min}) = \overline{L}$.

Assumption 1* replaces assumption 1. G are the minimal expenditures which are necessary to produce a particular public good, given the bureaucratic production efforts e_1, e_2 and the capital investments $2\overline{K}$. The joint-lobbying efforts aim at increasing the total departmental budget above the purely productive expenditures $G(\cdot)$. Only the bureaucrats know the precise technology which drives $G(\cdot)$, only they can tell apart G and L . (The only exception is the above-mentioned minimal level of public-good supply.)

Once again, the total budget finances the bureaucratic incomes plus the capital investments plus, possibly, pure waste,

$$B = G(e_1, e_2, 2\overline{K}) + L(x_1, x_2) \geq I + J + 2\overline{K}.$$

To understand this inequality properly, the reader may consider that a fully informed sponsor would appropriate a budget with $L = 0$, that is,

$$B = G(e_1, e_2, 2\overline{K}) = I + J + 2\overline{K},$$

where I and J were considered as compensations for the productive efforts e_1 and e_2 . The sponsor's lack of information enables the bureaucrats to induce $L > 0$, which partly may increase their incomes and partly may be used for pure waste.

Assumption 2 (antagonistic lobbying) and Assumption 3 (income schedules) remain unchanged. It is impossible to condition incomes on the amount of productive efforts because these are private information of the bureaucrats. The bureaucrats' objective functions also remain unchanged. In these objective functions there is still no need to explicitly consider the agents' disutilities from effort since the sum of all efforts is exogenous and normalized to unity and we do not assume that different kinds of efforts cause different disutilities.

Once again we assume that the agents first decide on the feasibility of the project. If the project is found feasible, each agent maximizes his utility with respect

to e_i and y_i considering the special constraints for this two instrument variables, and taking as given the efforts of the other bureaucrat. Let us present the optimization approach of agent 1, the extension to agent 2 is straightforward.

$$\begin{aligned}
 & \max_{e_1, y_1} \quad \theta_1 pB + (1 - \theta_1)I \\
 & \text{subject to} \\
 & e_1 \in [e_1^{min}, 1], \quad (\mu_{11}, \mu_{12}), \\
 & y_1 \in [0, 1 - e_1], \quad (\mu_{13}, \mu_{14}),
 \end{aligned}$$

where μ_{11} to μ_{14} are the Lagrangean parameters associated with the constraints. Completely new are the results which refer to the optimal choice of productive-effort levels e_i . The first-order conditions are different according to the type of income schedule. For agent 1, we obtain

$$\begin{aligned}
 I = \bar{I} : \quad & p[G_1 - L_1]\{\theta_1\} \gtrless 0, \\
 I = I(B) : \quad & [G_1 - L_1]\{p\theta_1 + (1 - \theta_1)I'\} \gtrless 0, \\
 I = I(pB) : \quad & p[G_1 - L_1]\{\theta_1 + (1 - \theta)I'\} \gtrless 0. \\
 \forall I : \quad & \mu_{11}(1 - e_1) = 0, \quad \mu_{12}e_1 = 0 \quad \mu_{11}, \mu_{12} \geq 0.
 \end{aligned}$$

Analogous conditions hold for agent 2. Since in (A.3) to (A.3) the terms in braces are always strictly positive, we have the following interesting result. Of course, the quantities of productive effort will differ according to the income schedule the bureaucrats face. *However, the qualitative results are independent of the income schedule.* There will be no lobbying at all if the bureaucrats can most easily increase their budget by increasing the amount of the public good ($G_1 > L_1 \Rightarrow e_1 = 1$). On the other hand, the bureaucrats will only exert minimal effort if lobbying is the easier way to maximize the individual budgets ($G_1 < L_1 \Rightarrow e_1 = e_1^{min}$).

When it comes to the differentiation with respect to the antagonistic-lobbying efforts y_i , we recognize that the results are qualitatively the same as in sections 3 and 4. For agent 1, we obtain the following first-order conditions:

$$I = \bar{I} : \quad [p_1B - pL_1]\{\theta_1\} \gtrless 0,$$

$$I = I(B) : \quad [p_1 B - pL_1]\theta_1 - (1 - \theta_1)I'L_1 \begin{matrix} \geq \\ \leq \end{matrix} 0,$$

$$I = I(pB) : \quad [p_1 B - pL_1]\{\theta_1 + (1 - \theta_1)I'\} \begin{matrix} \geq \\ \leq \end{matrix} 0.$$

$$\forall I : \quad \mu_{13}(1 - y_1) = 0, \quad \mu_{14}y_1 = 0, \quad \mu_{13}, \mu_{14} \geq 0.$$

These conditions imply the same qualitative results as (11) to (13) in the text. The only difference consists in L_1 replacing B_1 . The explicit consideration of productive efforts e_i changes the boundaries of the antagonistic-effort levels, but otherwise we face the same type of corner solutions. Therefore, all qualitative results of the text hold as well if the total time endowment for lobbying is endogenized.

Notes

²²This proof follows Bös and Kolmar (2000).

²³For the hypothetical Nash equilibrium of stage 1 a similar proof holds.

²⁴For the hypothetical Nash equilibrium of stage 1 a similar proof holds.

²⁵Note that Assumption 2 excludes a sharing rule with equal shares regardless of the antagonistic efforts, that is, $p(y_1, y_2) = 1/2 \forall y_1, y_2$. Such a sharing rule would not guarantee an equilibrium with $B = x_1 + x_2$ for all possible realizations of pB and $(1 - p)B$ given $B = \overline{I} + \overline{J} + 2\overline{K}$.

²⁶Compare Table A.1 in Bös and Kolmar (2000).
